The figures given in Table 13 show that the water at the Narrows was on this occasion three-fourths as salt as the sea; at the Battery nearly two-thirds as salt, at Yonkers nearly one-third as salt, and at Peekskill, 50 miles from the Narrows, about 6% as salt as sea water. The difference in the amount of chlorine found from hour to hour at any one station were comparatively slight, a care-
67 ful examination of the original data indicating that the mixing of salt and fresh water was not going on violently in the vicinity of New York as was the case on the day when the samples were taken for Table 12.

From these studies it is evident that the water of New York bay is not composed of fresh and salt water in any fixed proportion. It changes with the season. In the Lower bay it has been found to range from about 20% to 100% sea water according to the location of the point with reference to local sources of dilution and the amount of land water coming down the various large rivers. A fair average for the Lower bay, under ordinary conditions of weather and beyond the range of local dilution, is probably about 75%.

The water of the Narrows has been found to vary from 43% to 77% sea water, the majority of samples averaging about 65% sea water. At the Battery the samples have ranged from 15% to 69% sea water, with an average in this vicinity, under what appear to be fairly normal conditions, of about 45%.

The lower Hudson is the scene of the widest variations in the proportion of salt. In the foregoing tables it is shown that the Hudson at Spuyten Duyvil has ranged from an hourly average of 5% to an hourly average of 44% sea water for a whole day. There may be as much salt sometimes at Croton Point, as there is at others at the Battery, 33 miles away. In fact the upper limit of brackish water may be found anywhere between Yonkers and Poughkeepsie. The cause of these differences is to be found largely in the rainfall, for this furnishes the land water which flows down the Hudson and tempers the salt. In the Spring, when the discharge of the river is at its height, large quantities of fresh water

force the salt water downward toward the sea; in the late
65 Summer, when the rainfall is slight and in Winter, when the tributary streams are frozen, the salt water creeps up the Hudson to a surprising distance. Between Yonkers and West Point the limit of salt is continually fluctuating. Every tide affects it here, and as the wind may raise the water of the bay more than the tide itself, every storm has an appreciable effect in advancing or retreating the line. The flow of the currents through the Narrows, East river and Hudson seems to have little influence upon the saltness of the water in those vicinities, except at seasons when the Hudson is discharging large quantities of fresh water, when the action of the tides produces a marked effect.

b—The Phenomenon of the Underrun.

So far we have considered only the quality of the water at or near the surface. There is reason to believe that the condition of the water at the bottom is somewhat different from that at the top. Owing to its greater mineral contents the water of the sea is about 2½ times heavier than fresh water, and this difference tends to keep the two apart. The sea water seeks the bottom and the river water the top of the bay and river.

The character of the water below the surface is of special interest in this investigation for the reason that salt water tends to precipitate sewage, causing a part of its solid ingredients to settle toward the bottom. Here the water is not so capable of disposing of the sewage inoffensively. Theoretically the water at the bottom should originally hold about the same amount of oxygen as the water at the surface, but as practically all of the oxygen must come from the atmosphere, the water at the bottom is not easily replenished in case of need. When sewage is disposed of in water, the oxygen of the latter is heavily drawn upon. If enough oxygen is not avail-
able for the beneficent bacteria which decompose, oxidize
90 and render it innoxious, they disappear and their place is taken by anaerobic germs which carry on putrefaction with the production of offensive odors. Examples of this kind of sewage disposal may be seen along the water fronts of New York wherever the sewers fail to discharge into an active current, a condition of affairs which has caused considerable annoyance and led to the removal of many sewer outfalls to the outer ends of the piers.

Observations begun in 1858 show that there is sometimes a layer of distinctly salt water beneath the brackish water in the Hudson for many miles above New York. Some persons believe that there are pockets and potholes in the bottom of the channel in which salt water and sewage accumulate, until a heavy rainfall causes a rush of water down the Hudson which clears them out. This deep current is called the "underrun."

The underrun of salt water may be and usually is quite independent of the surface currents. In fact it is often directly opposed to them; there are often two distinctly opposite currents one above the other, flowing at the same time. At a gauging station established by the United States Government in 1858, between

Bedloes, now Liberty, Island and Governors Island, the velocity of the underrun moving up the river was found to exceed the velocity of the surface current moving toward the sea. The daily progress of the underrun was 21 miles, at a depth of 68 feet.

It is obvious from this and from the fact that the surface water becomes more and more salt at points up the Hudson during dry weather, that the net result of the backward and forward movement of the tides, may sometimes be to carry such elements of sewage as are not assimilated up the river, and not out to sea, as
70 is commonly supposed.

The following extract from the report of Prof. Henry Mitchell, contained in Appendix 15 of the report of the United States Coast and Geodetic Survey for 1887, p. 308, gives the opinion of the Government observers on the sanitary significance of the underrun:

"It would seem that the drainage of New York city must be storing up in August and September at the bottom of the Hudson. Some simple tests for sulphides which we employed when the underrun was first discovered, indicated that the mixture of sea and river water was recent. No 'spoiled' water in the potholes of the great central channel was found. Happily for the communities along the lower Hudson, the floods and freshets occur often enough to purge the great trench above New York city of sea water and sewer water in spite of the long inland journeys which these are prone to take in late summer and autumn—and perhaps winter."

c—Capacity of the Water of the Harbor to Digest Sewage.

If the foregoing conclusions are correct, the sewage which enters the bay is not disposed of by being carried to sea, but is assimilated by the water of the bay itself. This assimilating process is one of oxidation in which the bacteria play an important part.

Experience and experiment have shown that the digestive capacity of a water for sewage depends largely upon the supply of oxygen which the water contains. If a sufficient supply is not available, the sewage putrefies, giving off offensive odors.

Compared with fresh water streams or the ocean, the conditions in New York bay are not favorable for the disposal of sewage by assimilation. The constantly changing proportions of salt are opposed to the existence of a definite and permanent fauna and flora, and the phenomenon of the underrun shows that there is an absence of the vertical currents which are necessary for a con-
71 tinued supply of oxygen to the lower depths where the precipitating properties of the salt water are apt to carry more or less of the sewage.

The amount of sewage which can safely be discharged into fresh water is not a measure of the amount which salt water can dispose of satisfactorily, the digestive capacity of salt water being much less than that of fresh. Experiments carried on recently by Harry W. Clark for the Committee on the Charles River Dam, show that salt water normally holds less oxygen than fresh water, and that putrefaction, with the production of the exceedingly offensive gas,

sulphuretted hydrogen, is likely to occur when sewage is mixed with salt water which has not a sufficient supply of oxygen to enable the aerobic bacteria to carry on their work.

The sewage which now flows into the bay enters it in the most favorable manner possible, that is, in comparatively small amounts and at a great number of points. This aids in its general diffusion, without which no effective purification could take place.

It is impossible to say how much sewage could be discharged into New York bay without saturating it, that is, causing its supply of oxygen to become exhausted so that offensive putrefaction would become general. Already there are certain restricted localities where the water is decidedly offensive to the sight as well as to the smell. There, however, the tidal currents are sufficient to promptly carry the impurities to the main channels and there disperse them, there as yet, no trouble.

The amount of organic matter discharged into the rivers and bay in the vicinity of New York is not known with exactness, but it can be approximately determined from estimates of the amounts 72 of sewage discharged and the rainfall. The quantity of sewage discharged into the waters in the neighborhood of New York has been found to be about 455 million gallons per twenty-four hours, and the amount of drainage due to rainfall, estimated on the basis of 42 inches of rain per year and a runoff of 75 per cent, over an area of about 162 miles, is about 243 million gallons. These added together make a total of 698 million gallons of drainage wastes which the rivers and harbor receive daily.

There are no data to show the composition of this drainage, but if its composition is similiar to that of Worcester, Mass., the only American city whose mixed house and street sewage have been carefully analyzed, there are 1½ tons of solid, dry sludge for every million gallons, or 1,047 tons in it all. Of this, about one-half is organic matter.

Considered as a whole, there are no indications that the bay is being taxed beyond its capacity nor that it cannot digest considerably larger quantities of sewage, provided they are added properly, that is, through a sufficient number of outlets sufficiently far apart. What would happen if a very large amount of sewage were to be discharged at a single point is not ascertainable, but there is reason to believe that it would not be disposed of without the production of conditions which would be very objectionable if not intolerable. The chief danger is that it would not commingle promptly with the water surrounding it, in which event it might be carried to inhabited shores, creep up the Hudson with the undertow, or rise to the surface and there form an unpleasant, discolored area, as now happens in the harbor of Boston.

In considering the capacity of the bay to digest sewage, careful account should be taken of the future pollution to which it 73 will necessarily be subject as a result of the increase of population of New York city and the municipalities on its shores. Accepting the estimates of Mr. John R. Freeman, who has given very close attention to this subject of population in connection with

his studies of the future water supply of New York, it appears that the population of this area will be about double that of the present time in the year 1930. If the amount of sewage increases in proportion to the population, and the rainfall remains constant, the total increase in the amount of drainage entering the waters about New York will be about 65 per cent.

C—Industries Affected by Pollution.

The industries of New York bay which stand in any danger of being injured by such pollution as now exists, or is at all likely to occur in the future, may be classified as follows:

a. Shad fisheries.
b. Shellfish industries.
c. The passenger transportation business.
d. Excursions and bathing beaches.

These will now be considered separately:

a—Shad Fisheries.

The shad fishing industry depends upon the annual migration of the shad, Clupia Sapidissima, from the sea up the Hudson river to spawn. The most important localities for shad fishing are in Westchester, Ulster, Dutchess and Columbia counties, beside which the catch in the immediate vicinity of New York, by citizens of this State, is insignficant. Still, as the fish which are caught farther up the river must all pass through the Upper bay and lower Hudson, they are to some extent exposed to such conditions as there
74 exist. The fish begin to ascend the river in early spring. Gill nets are set for them in those parts of the river which are moderately shallow, the shoal water in the Upper bay known as the Jersey Flats being one of the spots favored by the fishermen.

It is said that some shad have been caught near the entrance of the Kill von Kull which have, when cooked, tasted strongly of kerosene, and that the discharge of liquid refuse in this vicinity from large industrial establishments has been the cause. Whether this is true or not could not be verified.

The following statistics of the shad industry in the vicinity are taken from a report of the United States Commission of Fish and Fisheries for 1902, *pp.* 449.

Table 14. Yield of shad in the vicinity of New York bay and credited to citizens of New York State in 1901.

County.	Pounds of fish.	Value.
New York	3,600	$250
Kings	45,975	2,715
Richmond	118,700	6,360
Total	170,275	$9,325

When it is considered that the shad industry of New York State yielded in 1901, 3,432,472 pounds of fish, valued at $110,682, and

was greater in that year than in any year since 1888, it does not seem likely that any pollution now in sight will do this business any harm.

b—Shellfish Industries.

The upper part of New York bay once supported oyster beds which extended from Staten Island to above Newburgh. Bedloe's Island, now called Liberty Island, was known as Oyster Is-
75 land and two small reefs just south of it were called the Little Oyster Islands. The oysters occurred here naturally and were reckoned a considerable source of wealth. They were so plentiful that the public was allowed to gather them with little or no restriction, until to-day these extensive grounds have become exhausted.* At the present time the cultivation of oysters in the bay is carried on almost exclusively below the Narrows. The Jersey Flats still furnish a small amount of natural seed, but it is doubtful if any market oysters are taken there. Attempts to raise seed in the vicinity of Piermont, just above the Palisades, recently, resulted in failure.

The value of the oyster beds in New York bay below the Narrows is very large. The principal grounds are owned by the State, on the southeast shore of Staten Island, and are let out at a nominal rent to those who apply for the privilege of cultivating them. Nearly the whole shore from a point near the mouth of the Raritan river to the neighborhood of Hoffman Island is now under cultivation, the total area of the beds being estimated at nearly 30 square miles. Prominent oystermen have estimated the yield from these islands at 500,000 bushels per annum; the Bureau of Shell Fisheries of the Forest, Fish and Game Commission has estimated it at more than four times this, and the United States Commission of Fish and Fisheries has estimated the yield at about 300,000 bushels for 1901. The value of these oysters is commonly taken to be $1 per bushel, although they sometimes bring a higher price.

76 Some clams or quahogs are taken in the same localities, but the only estimate of the quantity of these shellfish is that given by the United States Commission of Fish and Fisheries, which places the annual output at 21,900 bushels.

Table 15 gives details of the oyster business in this region as given by the Government authorities.

Table 15. Extent of the oyster and clam fisheries of Richmond county, N. Y., in 1901, as given by the United States Commission of Fish and Fisheries.

---

* NOTE.—That the pollution of the waters about New York by sewage, factory drainage and garbage have also done much to destroy the natural oyster beds in this vicinity, is stated in reports of investigations of the oyster industry made in 1885–1888 by the Commissioner of Fisheries of New York State, and published as Assembly Documents No.'s 85, 1885; 28, 1887, and 37, 1888.

Oysters, seed, Private areas	6,000	3,000
Total products	327,841	$298,532

The foregoing table does not represent the whole product of shellfish from New York bay, there being small oyster grounds and extensive clam beds in Gravesend bay, within the limits of New York city. Other localities where shellfish are taken in the vicinity
77 of New York bay, are Newark bay, Raritan river, the bend of the horseshoe, and the mouth of the Shrewsbury river. There are extensive natural seed beds in the Arthur Kill. Probably 500,000 bushels of market oysters are taken annually by citizens of New York State from the waters of the harbor within the limits of this State, and the same quantity by citizens of New Jersey from practically the same waters within the State of New Jersey.

Our analyses show that most of the oysters grown in the Lower bay are not dangerously polluted, but that those which are taken from contaminated water are practically certain to be contaminated themselves.

The oysters taken from the Staten Island beds are not always shipped direct to market, but are first taken to some convenient stream of fresh or brackish water and there allowed to remain from high to low tide. In this way the size of the oysters is greatly in-

creased. Some of these "drinking" places, as they are called, in the vicinity of New York bay are among the worst to be found anywhere. One, known as Lemon Creek, on the southeast side of Staten Island, drains a populated area of 2,010 acres and has numerous privies and other sources of pollution on its banks. Samples of water and oysters taken from the mouth of this stream have been shown by our analyses to be greatly polluted. Another, and if possible, more dangerous "drinking" ground is situated at Tompkinsville, Staten Island. The stream which furnishes such fresh water at this place affords, flows from a thickly populated area of 2,960 acres. The sewage which is discharged into the Kill von Kull on both sides of this place, within a distance of three miles, exceeds 7,000,000 gallons per 24 hours. During the season prob-
78 ably ten thousand bushels of oysters are sometimes treated here per day. Sloops come not only from the neighborhood of New York, but often from very distant points to "drink" their oysters before offering them for sale at the markets. Outbreaks of typhoid fever have been traced to oysters treated elsewhere in this way, and the "drinking" should be forbidden by law.

c—Passenger Transportation Business.

The business of transporting passengers across the bay is already large and is constantly increasing. The majority of the passengers are commuters who do business in one part of the city and live in another, or in the country, and go back and forth every day on the boats of the ferry companies.

The pollution of the bay, if unrestrained, might affect the business of these companies in two ways. The number of passengers would decrease if public health was endangered by the trip, or if the water became markedly offensive to the sight or smell. Fortunately, no amount of pollution which the growth of the cities bordering on the bay will make necessary is likely to affect the health of persons crossing the water, although it is quite conceivable that the discharge of a large amount of sewage in one spot might cause a local nuisance which would divert travel to more agreeable routes.

The extent of the transportation business in the waters about New York may be understood by the following table, compiled from data courteously supplied by the United States Steamboat Inspection service:

79 Table 16. Number of passengers carried by the principal ferries in the vicinity of New York in 1903.

Name of ferry company.	Number of passengers.	Route across.
Brooklyn Ferry Company...	33,911,317	East River.
Hoboken Ferry Company...	32,000,000	Hudson River.
Union Ferry Company.....	30,687,096	East River.
Penn. R. R. Company.....	30,337,493	Hudson River.
Erie R. R. Ferries.....	16,667,252	Hudson River.
L. I. R. R. Ferries.....	15,639,250	East River.
C. R. R. of New Jersey Ferries	10,700,862	Hudson River — New York Bay.
S. I. R. T. Ferry.....	7,929,000	New York Bay.
W. S. R. R. Ferries.....	5,873,886	Hudson River.
N. Y. and E. R. Company...	4,309,700	East River.
Nassau Ferry Company.....	2,680,000	East River.
N. Y. & S. Brooklyn Ferry Company	1,720,000	East River and New York Bay.
Fort Lee Ferry.....	1,705,659	Hudson River.
Total.....	194,161,515	

Of the total number of passengers shown in Table 16, about 8,811,000 traveled directly across the center of upper New York bay.

d—Excursions and Bathing Beaches.

For somewhat less than six months of the year excursion steamers ply about the bay and carry large numbers of passengers in search of pleasure and health. Most of these steamers have fixed destinations, such as picnic grounds and bathing beaches, but some merely sail about without landing their passengers. The total number of passengers carried by excursion steamers in the New York district in 1903 was about 2,300,000. It is obvious that any condition of the water which is capable of injuring the business of transporting commuting passengers is certain to do at least equal injury to the excursion business.

A large proportion of the people who patronize the excursion steamers do so in order that they may reach in a pleasant and expeditious manner what are called "day summer resorts." These are in reality extensive bathing beaches with hotels, restaurants and a great variety of amusement places. The largest day summer
80 resort near New York is Coney Island, with a daily attendance estimated at from 200,000 to 400,000 people. Others are Midland Beach and South Beach, on the Staten Island shore. These are all located in the Lower bay, somewhat beyond the Narrows. Millions of dollars have been invested at these day summer resorts to attract visitors and they are deservedly popular. They would suffer material loss in patronage if the water became sufficiently polluted to affect health.

Bathing is far more common in the Upper bay than is generally supposed. In the year 1903 over 3,000,000 baths were taken in the floating bath houses maintained by the city of New York on the water front.

D—Project of the Passaic Valley Sewerage Commission.

It is proposed by the Passaic Valley Sewerage Commission, acting under authority of the Legislature of the State of New Jersey, to construct a large trunk sewer which shall collect the sewage of an extensive and populous district and empty it into the waters of New York bay. The point chosen for the outfall of this sewer is about three-quarters of a mile north of Robbins Reef light, on the western edge of the main channel of the Upper bay. The discharge is to be continuous. The ultimate capacity of the sewer is to be 345,830,000 gallons per 24 hours. This is approximately 50% of the total amount of sewage from houses and streets which drains into the bay at present.

A careful examination of the published reports of the engineers whose opinions have been asked by the Passaic Valley Sewerage Commission with reference to the possibility that the proposed sewer will create a nuisance to persons or property adjacent to the
81 bay, shows that it has generally been assumed that the tides cause a more perfect flushing and cleansing than our present studies indicate. In the foregoing sections of this report we have not found that the water of the bay is renewed at every tide. Analyses have shown that there is not ordinarily a great deal of difference in the quality of the water at ebb and flood tides. Samples taken near the Narrows on the flood tide have been far from as pure as the sea. Our studies of the diffusion of the salt and fresh water in the bay lead to the conclusion that the rise and fall of the tides result largely in a backward and forward movement of the same water and that the actual renewal of pure sea and river water, except during freshets or storms, is far less than has been supposed.

In considering the possibility that the sewage of the Passaic Valley District can be discharged into New York bay without creating a nuisance, therefore, we should reject the idea that it will be promptly carried to sea and consider the probability that it can be assimilated and digested by the water of the bay in the bay and rivers about New York.

We have seen elsewhere in this report that the digestive capacity of New York bay is very large; larger than would probably be necessary for the assimilation of the sewage which will probably need to be discharged into it in the next twenty-five years. This conclusion is not based upon the assumption that sewage would be brought to the bay from communities remote from the shores of the bay, nor upon exceptional conditions such as the discharge of an enormous quantity of sewage at any particular points. Such conditions if not prevented, might easily lead to local nuisances and overcharge the water with organic matter which could only putrefy.

82 What appears to be an erroneous assumption in the reports of the engineers of the Sewerage Commission is the theory that the sewage from the Passaic Valley sewer will be rapidly diffused throughout the bay. It does not seem possible that this diffusion could be as rapid as the diffusion of smoke and vapors in the atmosphere, and we have in tall chimneys at Bayonne and Fort Lee

sufficient illustration of the fact that smoke and vapors can travel several miles without commingling with the atmosphere and disappearing from sight. Is it probable that the sewage of the Passaic Valley District would be so rapidly diffused that it would not be easy to recognize it from the decks of the boats which ply through the harbor? Precedents for the discharge of so much sewage at a single point are not numerous, but perhaps the experience of Boston may be cited as an answer.

At Deer Island, near the entrance of Boston harbor, there is an outlet of a sewer which discharges 38,300,000 gallons of sewage per day. The water near this outlet is discolored over an area of about 350 acres. When the sewage has traveled about 1⅛ miles from the outlet, which it does in about 1¼ hours, the discoloration disappears.

At Moon Island, also in Boston harbor, there is a sewer outfall which discharges 22,000,000 gallons of sewage in ¾ hour, the discharge being discontinuous and so regulated that the sewage is emptied into the harbor only during that period of the outgoing tide which is most likely to carry it to sea. The discolored area in this case is about 750 acres. Because it is not all perfectly fresh, some of this sewage is septic. It is offensive to the sight and smell over two-thirds of the discolored area.

If the conditions in Boston harbor are to be taken as an indication of what might happen in New York bay, it appears that
83 the discharge of the greater quantity of sewage which the Passaic Valley District Sewerage Commission has to deal with, would discolor about 3,000 acres or 4.7 square miles.

Setting aside, therefore, the questions of health and the ultimate saturation of the bay with organic matter, this local discoloration, with possibly the creation of offensive odors, directly in the path of ferry boats, excursion steamers and the Atlantic shipping would be a cause of serious annoyance. But it is by no means certain that the discharge of so much sewage in the centre of the tidal basin of the Upper bay would not bring about conditions injurious to the public health. The proposed outfall is within ½ mile of the pierhead line and 1¼ mile of the line of solid filling established by the U. S. Government on the New Jersey shore. It is within two miles of Staten Island and of Liberty Island, a popular point for excursions, and of Governors Island, the headquarters of the U. S. army in this district. The Brooklyn shore is about two miles away. Ellis Island, the headquarters of the U. S. Immigration Bureau, is within 2½ miles. The southern end of Manhattan is about 3¼ miles away. Immediately to the west, are the Jersey Flats comprising about 8 square miles of muddy bottom lying under about 1 to 7 feet of water at low tide. The extensive improvements of the Pennsylvania railroad are close to the proposed outfall on the north.

Summarizing the matter, it does not seem likely that the additional amount of organic matter which would be contained in the sewage which the Passaic Valley Sewerage Commission would discharge into the bay would overtax the digestive capacity of the water provided that it could be added in a way which would insure

its immediate and thorough diffusion throughout the waters of the harbor and rivers. The effect would undoubtedly be to increase the permanent effects of pollution which are already measurable and which make the waters in the vicinity of the bay less desirable than they should be for bathing and the cultivation of shellfish. But it is not believed that a complete and satisfactory diffusion of the sewage lies within the range of practical possibility. A large number of the comparatively small sewers which discharge into the bay, create local nuisances near their outfalls, and experiment shows that the disposal of sewage into water which has not sufficient oxygen to permit of its prompt decomposition by the bacteria, results in a particularly offensive kind of putrefaction. The experience of Boston is believed to furnish a fair illustration of the kind of local nuisance which could reasonably be expected if the present plan of the Passaic Valley Sewerage District Commission was carried out. The fact that the sewage at Nixon Island discharges at the surface, and at Deer Island 9 feet below the surface at high tide, while the Jersey sewer is to empty into the bay at a depth of 45 feet, seems not to have sufficient bearing upon the conditions to alter this conclusion.

Conclusions.

The studies which have been outlined in the foregoing pages have led to certain definite conclusions which, for convenience, may be briefly summarized as follows:

(1.) The effects of the present pollution of New York bay, although not great, are nevertheless measurable.

(2.) A careful study of the proportions of sea water and fresh water in the bay and rivers about New York shows that the sewage of New York city is not promptly flushed out to sea, except during freshets in the Hudson.

(3.) The water of the incoming tide is not ordinarily much purer than the water of the outgoing tide in the Upper Bay.

(4.) It is probable that most of the sewage which enters the bay is disposed of in the bay by animals and plants, chiefly the bacteria which live in this water.

(5.) The most useful effect of the tide is its production of currents whereby the sewage becomes mixed and diffused.

(6.) The drainage which now enters the bay does so in the most favorable manner possible for diffusion; that is, from a large number of outlets situated along an extensive shore line.

(7.) How much sewage and other organic matter can be emptied into the bay without killing those forms of life which now destroy it, and so creating a general nuisance, it is impossible to say. This is a matter of great importance, but its proper study requires analyses and experiments which have been beyond the reach of this commission.

(8.) Compared with fresh water streams or the ocean, New York bay is not a favorable place for the inoffensive disposal of sewage.

(9.) Should the bay become overloaded with sewage, the odors which will arise from it will be particularly offensive.

(10.) The total amount of solid matter which now enters the bay with house and street sewage, every 24 hours, is approximately equivalent to 1,047 tons of dry sludge. About one-half of this is organic matter.

(11) The bay is not likely to be polluted to such an extent that a general nuisance will occur for 25 years at least, if it is used solely for the discharge of sewage from the communities which are adjacent to its shores.

86 (12.) Long before a general nuisance is produced, local nuisances will occur, as may be seen at present to a limited extent, where sewers and drainage from industrial works empty into still, or comparatively still water.

(13.) Observations made by the U. S. Government show that a distinct current of salt water sometimes runs up the Hudson under the fresher water, without respect to surface currents, and it has been suggested that this under-run carries sewage from New York city up the river and empties it into potholes or depressions in the bed of the channel, where it remains until washed out by freshets.

(14.) The oyster beds in New York bay are almost exclusively located on the southeast side of Staten Island and Gravesend bay.

(15.) Most of the oyster and clam beds are now free from dangerous pollution, although there are some on the Staten Island shore near the Narrows and the Kill von Kull, and a few in Gravesend bay, which are nearer sewer outfalls than is proper.

(16.) Our analyses of oysters and clams show that shellfish which are grown or immersed for some hours in polluted water become polluted themselves.

(17.) The increasing amount of pollution to which the waters of New York bay are subject makes it seem only a question of time when oyster culture will be driven from this locality; but with wise and careful protection, a large part of the present oyster grounds can be kept safe for some years to come.

(18.) The almost universal custom in this vicinity of "drinking," that is, bleaching and bloating oysters in polluted streams of fresh water, places all shellfish under suspicion of being contaminated.

87 (19.) The pollution of the bay has had no visible effect upon the number of fish caught in the vicinity of New York, although petroleum and other industrial wastes appear to have occasionally affected the flavor, and consequently the value, of small catches of shad.

(20.) The transportation of passengers on ferry boats is one of the most important industries connected with the bay, the number of passengers transported in the New York district in 1903 having been 204,000,000, and the number which traveled directly across the centre of the Upper bay, 8,811,000. This business would be seriously injured if the water became offensive to the sight and smell.

(21.) Unrestricted pollution of the bay would destroy the health-

fulness and attractiveness of the parks and recreation piers which have been built by the city of New York on the water fronts for the benefit of the poor.

(22.) Excursion steamers carried about 2,300,000 passengers to bathing beaches and other day summer resorts on or near the bay in 1903. The most important of these places are located a little beyond the Narrows in the Lower bay and represent a total investment of several million dollars. The pollution of the bay will eventually injure the healthfulness and business value of these resorts, unless restricted.

(23.) The project of the Passaic Valley Sewerage Commission of New Jersey, if carried out, would ultimately empty into the centre of the upper bay 345,850,000 gallons of sewage per day from a community not adjacent to the bay.

(24.) The proposed sewer, if put into service at once, would increase the amount of house sewage and storm drainage which enters the bay by about 50 per cent.

(25.) The natural increase in population of New York and vicinity will, by 1930, increase the present amount of pollution about 65 per cent.

(26.) If the New Jersey sewer is built, the pollution of New York bay will be more than doubled in the next twenty-five years.

(27.) Since the organic matters contained in the sewage which is emptied into the bay must be destroyed by assimilation in the bay, it is evident that the discharge of so much sewage as that proposed by the Passaic Valley District Sewerage Commission must first be diffused before it can be purified. It is by no means clear that the sewage would be so diffused before reaching inhabited shores.

(28.) Precedents for the discharge of so much sewage at one point, as contemplated by the Passaic Valley District Sewerage Commission, indicate that this quantity of sewage cannot be emptied into New York bay, in accordance with the announced plans of that commission, without producing a local nuisance.

(29.) Probably the nearest approach to the conditions which might be expected is at Boston. At Deer Island in Boston harbor, the discharge of 38,300,000 gallons of sewage per day causes the water about the outlet of the sewer to be discolored over an area of 250 acres. At Moon Island, also in Boston harbor, the discharge of 22,000,000 gallons of sewage in about ¾ hour discolors about 750 acres, about two-thirds of this area being offensive to the sight and smell.

(30.) If the conditions in Boston harbor are a fair example of what would happen in New York bay, the sewage from the outfall of the Passaic Valley sewer would discolor and render more or less offensive about 3,000 acres or 4.7 square miles of the most beautiful and most traveled part of New York bay. On calm days the sleek, or thin film of grease from this sewage might reach Liberty Island, Ellis Island, Governors Island and the Battery, or Brooklyn and Staten Island.

89 APPENDIX 4.

Legislative and Documentary History of the Passaic Valley Project, and Ocean Disposal of Wastes.

By Commissioner Olin H. Landreth.

Passaic Valley Sewerage Commission.

The Legislature of New Jersey on February 26, 1896, enacted a law (being chapter 7 of the Laws of 1896) entitled "An act for the construction of a general system of sewage disposal for the Valley of the Passaic river and the prevention of the pollution thereof." This law provided for the appointment by the Governor of three citizens of New Jersey to consider the subject of the pollution of the Passaic river and for a general system of sewage disposal for the relief of the Passaic Valley. These persons were given power to employ engineering and other assistants and to report to the Legislature their conclusions, with maps, plans, methods of carrying out the work, an estimate of cost and a recommendation as to the method of apportioning the cost. The sum of ten thousand dollars was appropriated to defray expenses of this investigation.

A copy of this act in full is given on page 5, of the published report of the N. J. commission dated February 26, 1897, and forming item No. 2 of this synopsis. Governor Griggs appointed on April 21, 1896, as such commission, Messrs. Elias J. Marsh, M. D., H. C. H. Herold, M. D., and William T. Hunt, who prepared and submitted to the Legislature on February 26, 1897, their report of the Passaic Valley Sewerage Commission which forms the following item.

90 Report of the Passaic Valley Sewerage Commission Submitted February 26, 1897.

The commission organized with the following officials and advisers: E. J. Marsh, M. D., treasurer; W. D. Scott, secretary; Joseph Could, counsel; Alphonse Fteley, consulting engineer; C. E. A. Jacobsen, engineer; H. E. Abbot, A. W. Cuddleback, Robert F. Sayles, James A. Wylie, assistant engineers; Herbert B. Baldwin, chemist, and Richard N. Connolly, M. D., bacteriologist.

The report of the commission contains the individual reports of the engineers, the secretary, the chemist and the bacteriologist together with the general conclusions and recommendations of the commission including the draft of "An act providing for the purification of the rivers and streams of water within this State and to prevent the pollution of the same."

Act to Prevent the Pollution of the Upper Passaic River.

The Legislature of New Jersey enacted on March 24, 1897, (forming chapter 35 of the Laws of 1897) an act to prevent the wilful pollution of the Passaic river and the tributaries thereof above the Great Falls of the Passaic river at Paterson. This law was evidently intended to protect the purity of the potable water supply of the East Jersey Water Company and has no very important bearing on the efforts to reduce the pollution of the lower Passaic Valley.

Legislative Committee.

Owing to a strong opposition to the terms of the draft of the bill recommended by the commission of 1896 the bill was not brought up for passage but in place thereof an act was passed authorizing a committee of members of the Legislature to study the subject of and to report at the next session what should be done in the matter. The committee consisted of Senators Robert Williams, and W. M. Johnson and Assemblyman T. C. Wildman. During 1897 this committee held public meetings and listened to arguments for and against the proposed legislation. In the spring of 1898 the committee reported as a result of its labors that the whole matter ought to be studied again by a new commission and presented a bill providing for a commission of eight persons, three of whom were to be members of the original commission of 1896. The bill was passed and Governor Voorhees on Aug. 3, 1898, appointed the following commissioners: Mr. William T. Hunt, Dr. H. C. H. Herold, Dr. E. J. Marsh, Hon. John Hinchliffe, Dr. James A. Exton, Hon. Charles W. Fuller, Hon. Charles F. Harrington, and Mr. William Kent.

State Sewerage Commission.

The Legislature of 1899 on March 24th enacted a law (forming chapter 210 of the Laws of 1899) entitled "An act to prevent the pollution of the waters in this State by the establishment of a State Sewerage Commission, authorizing the creation of sewerage districts and district sewerage boards and prescribing, defining and regulating the powers and duties of such commission and such boards." This act provided for the appointment by the Governor of five citizens of the State to compose the "State Sewerage Commission," the duties of which commission are to investigate the various methods of sewage disposal and to investigate all complaints of pollution of the waters of the State and to advise as to the best methods of sewage disposal in order to prevent such pollution and to pass on, approve or disapprove of all plans for sewage disposal into the waters of the State before such systems can lawfully be built and the sum of five thousand dollars was appropriated to enable the commission to carry out the provisions of the act. The act also provided for the formation of "sewerage districts" and

the appointments of "sewerage boards" each board to comprise two members of each municipality within the district to be appointed by the governing body of each such municipality and one member to be appointed by the State Sewerage Commission. These district boards were to be considered as corporate bodies and were given powers to investigate, design, construct, maintain and operate systems of sewerage and drainage or systems of sewage disposal works or both and were given the power to condemn and appropriate lands and to issue bonds.

This act was re-enacted in a somewhat amended form by the Legislature of 1900 (forming chapter 72 of the Laws of 1900.)

It is to be noted that the functions of this State Sewerage Commission are general and are not confined to the Passaic Valley.

The first commissioners to be appointed under this act were as follows: Charles F. Harrington, Hon. John Hinchliffe, Wm. T. Hunt, Charles W. Fuller, David L. Wallace.

This State Sewerage Commission has submitted several annual reports referred to as follows:

Annual Report of State Sewerage Commission for 1899.

This report forms document No. 48 of volume V. of Legislative Documents for 1899. As no appropriation was made for the expenses of the commission no engineering investigations were made during the year, but the commission gathered a large amount of information concerning the sewerage of the cities and villages of the State on circular blanks issued by the commission. The
93 commission recommended to the Legislature that additional powers be given the commission by which they might compel the abatement of existing pollution and also recommended that authority be given to two or more municipalities to cooperate in providing sewerage and disposal. The commission also submitted a draft of a bill amending the existing law (chapter 210 of the Laws of 1899) so as to provide the above and several other proposed features.

Annual Report of the State Sewerage Commission for 1900.

This report comprises document No. 49 of volume V. of Legislative Documents for 1900. The Legislature of 1900 amended the original law establishing the State Sewerage Commission and re-enacted it as chapter 72 of the Laws of 1900. On June 4, 1900, the State Sewerage Commission adopted a resolution as follows:

Resolved, That under authority of chapter 72 of 1900 that prior to June 1, 1904, the municipalities of Paterson, Passaic, Rutherford, Newark, Orange, East Orange, Montclair, Bloomfield, Glen Ridge, Kearney, Harrison and East Newark now polluting the waters of the Passaic river with sewage, must cease to pollute the waters of the said river and make such disposal of the sewage and other polluting matter of such municipalities as shall be approved by this commission.

During the year the commission received and considered a number of complaints and petitions and passed on plans for sewerage and sewage disposal for a number of municipalities in the State. The subject of sewage disposal in Great Britain and France was investigated by Chairman William T. Hunt who inspected and reported on the system in use in London, Paris, Leeds, Manchester, Glasgow and Edinburgh. No extended engineering investigations were made by the commission during this year owing still to lack of funds.

Annual Report of State Sewerage Commission for 1901.

This report forms document No. 49 of volume V. of Legislative Documents of 1901. Governor Vorhees transferred to the commission eight thousand dollars from his emergency fund, which enabled the commission to undertake some engineering work. This work was all confined to the Passaic Valley problem as being the most important single sewerage problem in the State and consisted in the making of surveys and plans for the system of intercepting sewers extending from Paterson along Passaic river to Newark bay with plans for sewage disposal. A part of this work was undertaken by Messrs. Collin R. Wise, Robert M. Watson and William Ferguson, engineers, and the remainder by Mr. James Owen, C. E., and reports were submitted for these two divisions of the engineering work. These reports with the maps and plans accompanying them were then submitted to a board of consulting engineers comprising Messrs. Rudolph Hering, J. J. Croes and William M. Brown who examined and reported not only on the plans as already submitted, but also on alternate features. The conclusions of the board of consulting engineers were that the most efficient and economical system of disposal for the Passaic Valley from Paterson to Newark bay was a system of intercepting sewers without sewage treatment by which the entire sewage of the municipalities along the valley should be brought to New York bay. The commission also submitted a number of technical questions regarding the sewage disposal to Mr. H. W. Clark, chemist of the Massachusetts State Board of Health, and the report contains the answers of Mr. Clark on these questions. In addition to the Passaic Valley investigations the commission also considered the cases of a number of municipalities and streams throughout the State and ordered a number of municipalities to cease the pollution of certain streams at certain stipulated dates. The commission also approved during the year plans for sewerage and disposal for a number of municipalities in the State.

Annual Report of the State Sewerage Commission for 1902.

This report forms document No. 33 of Volume III, of Legislative Documents for 1902 submitted to the Legislature of 1903. The Legislature of 1902 having passed an act (chapter 48 of the Laws of 1902) establishing a separate sewer district for the Passaic

Valley and creating a commission therefor. The State commission devoted its energies to other portions of the State, placing the services of its members and the official records and material at the disposal of the Passaic Valley Sewerage Commission.

The Legislature of 1902 passed an act (chapter 49 of the Laws of 1902) which was approved March 27, 1902, providing that the Legislature might create and incorporate sewerage and drainage districts and providing for the appointment by the Governor of boards of sewerage commissioners of five residents of each such districts.

Passaic Valley District Sewerage Commission.

The Legislature of 1902 passed an act (chapter 48 of the Laws of 1902) which was approved March 27, 1902, entitled "An act to create a sewerage district to be called Passaic Valley Sewerage District."

The Governor appointed under these acts the following gentlemen to comprise the Passaic Valley Sewerage Commission:
96 Messrs. J. A. Lebkuecher, John Hinchliffe, Francis Child, Peter Houck and William McKenzie.

This commission organized on April 22, 1902, by the selection of Mr. J. A. Lebkuecher as chairman and Mr. John S. Gibson as clerk. On August 18th the commission appointed Mr. Rudolph Hering of New York as its chief engineer. This commission submitted its first annual report to the Legislature on January 23, 1903.

Annual Report of the Passaic Valley District Sewerage Commission for 1902.

This report was submitted on January 23, 1903, and contains besides the general report of the commission the report of its chief engineer Mr. Rudolph Hering and also the draft of the proposed bill which should more thoroughly provide for the carrying out of the sewerage improvements recommended by the commission.

The report of Chief Engineer Hering describes his surveys, examinations and conclusions on the study of two alternate general plans of improvement; namely, first a system of intercepting sewers extending from Paterson to Newark bay by which the sewage of this portion of the valley should be brought to a discharge into the waters of upper New York bay without purification; and second, a system of intercepting sewers, but in place of crude disposal in New York bay the use of one or more purification plants in which the sewage should be treated and the purified discharged into the Passaic river or Newark bay. Mr. Hering's conclusions favor the adoption of the former method. This system which is the one now authorized for construction comprises a main intercepting sewer extending
97 from a point near the Great Falls of the Passaic in the city of Paterson along the right and westerly bank of the Passaic river to a point in the city of Newark where it leaves the river and passes southeasterly through the city across the meadows

to a point on the shore of Newark bay about opposite West Bergen Point, where a main pumping station is to be located. Down to the site of the pumping station this is to be a gravity sewer, but two auxiliary pumping stations are proposed, one at Wallington and one at Lynhurst where sewage from low level sewers on the left bank of the Passaic river to be pumped across the river and into the main intercepting sewer. The pumping station on Newark bay is to force the sewage through two 6 feet diameter steel force mains under Newark bay and up into a gravity sewer which is on the eastern shore of Newark bay in Jersey City at the Morris and Essex canal. This gravity sewer, 13 feet in diameter, leads southeasterly along the canal to a point jutting out into New York bay near Panrapo where the sewer changes to the eight-feet steel pipe laid under New York bay up to a point about three-quarters of a mile northeast of Robbins Reef light in a depth of about 40 feet of water below the mean low tide.

This report also contains the draft of the bill which the commission recommended to the Legislature as being necessary to carry out the improvement proposed. This bill in a somewhat modified form was enacted on April 22, 1903.

The Act of April 22, 1903.

This act modified somewhat from the form recommended by the commission providing for the full powers of the comission and for the procedure to be followed in executing the sewerage improvement under consideration. One of the provisions of this act
98 was that before any work should be undertaken or obligations incurred the Passaic Valley District Sewerage Commission should investigate whether the proposed discharge of sewage into New York bay is likely to pollute the waters of said bay to such an extent or in such a degree as to cause a nuisance to persons or property within the State of New York, and required that the result of such investigation should be presented to the Governor with the opinion of the commission thereon and the reasons for their opinion; thereupon that the same should be considered by the Governor and the Attorney-General and that no work or further proceedings be taken unless the Attorney-General should in writing advise that no cause of action for damages or an injunction would arise in favor of the State of New York or any of its inhabitants by reason of such discharge of sewage into the waters of New York bay.

Special Report of the Passaic Valley District Sewerage Commission Submitted June 8, 1903.

Pursuant to the requirements of the law above quoted the Passaic Valley District Sewerage Commission investigated the subject and reported as their opinion that the discharge of the sewage from the proposed Passaic Valley sewer would not pollute the waters of New York bay to such an extent or to such a degree as to cause a nuisance to persons or property within the State of New York.

The commission submitted as a warrant for its conclusions copies of the written opinions of General Henry M. Roberts, George S. Greene, Jr., E. W. Harrison, O. H. Tittmann, William Barclay Parsons and Allan N. Spooner.

Governor Murphy's Authorization to Proceed.

Governor Murphy having examined the special report submitted by the Passaic Valley District Sewerage Commission referred
99 the same to Attorney-General McCarter for his legal opinion. The Attorney-General having examined the report and having further investigated the case advised the Governor that he found no legal objection to the building of the trunk sewer proposed and that in his opinion there would be no legal objection from the authorities of New York. Thereupon Governor Murphy authorized the sewer commissioners to proceed to the construction of the improvements contemplated.

Constitutionality of Act of April 22, 1903, Maintained by New Jersey Supreme Court.

The acts of 1902-3 were attached by writ of certiorari by the city of Paterson and a citizen of the State, the proceedings bringing up for review the validity of the resolution by the Passaic Valley District Sewerage Commission providing for an issue of $1,000,000 worth of bonds for preliminary work connected with the trunk sewer. The case was argued before three justices, two of whom sustained the constitutionality of the act, handing down their opinion July 23, 1904.

Act of April 22, 1903, Declared Unconstitutional by the New Jersey Court of Errors and Appeals.

An appeal was taken from the decision of the Supreme Court as rendered, and on March 6, 1905, the Court of Errors and Appeals, by a vote of ten to one, reversed the decision of the Supreme Court previously referred to, and declared the act of 1903 unconstitutional, as it is an attempt to delegate an essential element of the power of taxation; because if the taxing power could be deemed to be granted to the commission as a representative of the sewer district, the latter is not a political district of the State, and because if the Passaic Valley Sewerage District were a political district of the State it
100 could not be invested with the power to tax persons and property beyond its own limits.

New York State Law Authorizing an Inquiry.

On May 11, 1903, the Legislature of the State of New York enacted a law (being chapter 539 of the Laws of 1903) entitled "An act to authorize the appointment by the Government of a commission to investigate certain threatened pollution of the waters of New

York bay and making an appropriation for the expenses of such commission." On June 2, Governor Odell appointed as such commission Dr. Daniel Lewis, New York StateCommissioner of Health; Prof. Olin H. Landreth, Consulting Engineer, New York State Department of Health; Dr. George A. Soper, New York State Department of Health Representative at the Ithaca typhoid epidemic; Mr. Louis L. Tribus, Commissioner of Public Works of the Borough of Richmond, Consulting Civil and Hydraulic Engineer; and Dr. Myron S. Falk of New York, Instructor in Engineering in Columbia University.

The New York Commission after organization assigned certain lines of work to its individual members for investigation, which have been completed. The commission has held eight meetings, including two joint meetings with the New Jersey Commission and one public meeting on Staten Island; and has prosecuted several lines of inquiry. It has secured opinions on the legal questions bearing on the situation from the New York State Attorney-General and in March, 1904, submitted to the Governor a short progress report and asked for an extension of time in which to submit the final report, which was granted. It has also, at its meeting Feb. 10, 1905, formulated resolutions outlining the attitude which the commission should adopt toward the Passaic Valley sewerage question.

101 (B.)

Ocean Disposal.

Possible Ultimate Ocean Disposal of all Sewage Wastes from the Metropolitan Districts.

By Commissioner Olin H. Landreth.

The waters of the metropolitan district of New York and adjacent territory, constitute an invaluable heritage to its inhabitants. In their relations to commerce, these waters comprise the chief source of the strength of New York as a commercial metropolis; in their intersection and subdivision of the territory, while in outward appearance they are barriers to intercourse and transportation, in reality they are bonds uniting the several districts by an incomparable net-work of waterways throughout which the distribution of traffic and local transportation is carried on more conveniently, effectively and economically than if the waterways did not exist. In their climatic and sanitary relations they mitigate the heat of summer and offer breathing places and water-parks which no city could afford artificially to provide.

A large proportion of the metropolitan population of New York and adjacent territory passes twice daily over the one or another of the numerous waterways of the district; another considerable portion lives on or near the shores, and still other large numbers frequent the waters for bathing, for pleasure, and as an avenue to numerous nearby water resorts.

It is hardly needful to say that these waters, so important to the interests of the entire metropolitan district, lying both in New York State and in New Jersey, should be protected against impair-
102 ment and injury, and that existing conditions which injuriously affect them should as rapidly as possible be corrected. The most serious menace to these waters lies in their pollution by waters of a great urban district. This pollution has already reached a stage which warrants the closest consideration and the utmost concern. Even the present conditions, unsatisfactory as they are, would have been much worse but for continued past efforts and action looking to the protection of these waters. These restraining efforts have, however, been confined entirely to the matter of the disposal of street sweepings, combustible and noncombustible refuse, and garbage, and while much yet remains to be accomplished along these commendable lines of activity, a decided beneficial result has already been attained, in that a policy of treatment has been adopted, the work organized, the machinery set in motion, and the matter therefore in condition not only to yield beneficial results, but is also readily open to improvement and expansion.

These remedial activities, however, touch only one general class of pollution, namely: the city waste and garbage, which represent, when discharged into the waterways, the chief source of the sedimentary deposits and the visible suspended matter. No steps whatever have been taken, however, toward provision for the proper ultimate disposal of the sewage of this extensive district, if we except a few small municipalities whose aggregate population forms an insignificant part of the entire metropolitan population.

Up to this time the only thought has been how to conduct the sewage by the cheapest route to the nearest waterway, giving no thought whatever to its effect on the waterway and on adjacent waters. While the crude discharge of even moderate
103 amounts of sewage into the waterways is injurious to the waters, the harmful results increase at a more rapid rate than the increase in sewage discharge, and a limit is soon reached beyond which the discharge of sewage produces such obnoxious conditions of the waters as would be condemned by even low standards of quality.

The evidence now available seems to show that this limit is now not far distant and that any considerable increase in the present volume of sewage discharge into the waters of the district will be quite certain to produce decidedly aggravated conditions in those waters, which even present standards of excellence will condemn. Our present standards are, however, too low and the same advancement in public intelligence and taste which demands better public utilities, better sanitation and conditions for living and more exacting requirements in presentable and artstic surroundings, will soon insist on considering the present conditions of our metropolitan waters as repulsive and intolerable.

These two general facts, viz.: that the waters of New York and vicinity are already badly polluted, and that this pollution must of necessity rapidly become worse and soon reach an intolerable limit,

lead us to the problem of the remedy. Two general lines of relief present themselves for alternate consideration.

(1.) Improved sewage disposal for each local district or municipality within or near its own bounds.

(2.) A comprehensive scheme for ocean disposal of the crude sewage of the entire metropolitan district lying both in New York and New Jersey.

On a question of such importance and magnitude even general conclusions should be definitely adopted only after the most
104 able and exhaustive study and investigation, neither of which have the circumstances and conditions attending the appointment and work of this commission rendered possible. Such consideration, however, as it has been possible to give this question seems to point to the second plan, or that of crude discharge out to sea, as the most promising solution of the problem and one which on further investigation will probably be found most feasible and efficient.

The following conclusions appear, therefore, all that may properly be expressed:

(1.) The condition of the waters in and adjacent to the metropolitan district lying both in New York and New Jersey is rapidly approaching a limit in pollution which not only should not be passed, but which already calls for radical relief.

(2.) The two most apparent forms for such relief are:

(*a*) The installation and operation of individual systems of sewage disposal for each district or municipality and the discharge of the purified effluents into the waterways; or,

(*b*) The gathering of the crude sewage of the entire metropolitan district to several centers and the conducting or pumping of the same by one or more outlets or tunnels out to sea at a sufficient distance to insure against its return at flood tide to an extent that would injure the waters of the district.

This plan would probably make desirable the creating of an interstate metropolitan sewerage district created by treaty between the two States of New York and New Jersey and ratified by Congress, and having full administrative powers, with full provision for the questions of legislative, executive and judicial jurisdiction.

105 (3.) The conditions of appointment of this commission have not made it proper or possible to give this matter of relief that exhaustive study and investigation which the importance of the question demands, and therefore no final conclusions or recommendations can be made as between the above two plans of relief or possibly others, beyond a statement that the latter plan of ocean discharge of crude sewage of the entire district appears from the consideration given it to possess the greater advantages.

(4.) This commission is clearly of the opinion that an investigation of the best plan of relief for the waters of New York and vicinity is an urgent necessity and should be undertaken at once, and that pending the completion of such investigation and the inception of the plan of relief, no extensive or considerable changes or extensions should be made in the sewerage of such portions of the metropolitan

district as would be disturbed or sacrificed by the ultimate adoption and installation of a comprehensive scheme of improvement.

106 APPENDIX 5.

Need of the Metropolis District as a Whole and Desirability of Joint State Action.

By Commissioner Daniel Lewis.

The commission, from the very inception of its investigations, has been constantly confronted with the fact that the construction of the proposed Passaic Valley sewer is only one of many serious problems demanding legislative action for the protection of the waters of New York bay against sewage contamination.

The contention of the New Jersey Commission that because the bay is now receiving the raw sewage from 4,000,000 people, therefore an increase from an added population of 1,000,000 or more should be permitted, we believe to be untenable.

The bay is now an immense cesspool, which, like small receptacles of sewage, has a natural limit of capacity, beyond which lies danger to the health and comfort of the contiguous metropolitan district. The residents of New Jersey, who are expected to discharge their waste through the proposed sewer, are equally interested with the inhabitants of New York city in preserving the waters of the bay from further contamination.

It has been suggested, therefore, that a metropolitan sewerage district should be established, to include all sections in both New York State and New Jersey which now, or in future may sewer into the bay and its tributaries. This district, when authorized by joint State and Federal legislation, should be under the direction and control of a permanent interstate commission, with plenary power to control the discharge of all sewers hereafter constructed, as
107 well as the task of evolving a comprehensive plan for ultimately rendering the present chaotic and systemless method of sewage disposal, sanitary and suitable for all future requirements.

There seems to be no possibility of a comprehensive treatment of this great question through the action of various and constantly changing local authorities, acting independently. Manhattan may continue, as at present, to follow no system whatever, simply emptying a new sewer into North or East River at any place where grades permit, even though a recreation pier or a public bath may be already established at the same point. Brooklyn may, and probably will, carry its sewage into the sea, and thus ruin the bathing beaches within its limits, and pollute the great oyster beds therein, and Westchester county for forty miles from the city may contribute a large amount of sewage, while the State of New Jersey with its constantly increasing population, will add to its present outflow from year to year.

The necessity already exists for a central authority to not only direct, but also initiate, these great public works, upon which depend the beauty and healthfulness of the approximately 450 miles of shore within the metropolitan district.

Immediate action should be commenced to secure such an interstate commission, for the existing conditions must steadily approach the point where the public will demand relief.

In this country there is at present but one locality at all analogous to New York in this respect, viz., Boston, where a great metropolitan district empties its sewage into the harbor, but the difference in governing conditions is radical, as but one State is in control, while for New York harbor two great commonwealths would have to join forces.

108 England permitted the pollution of the Thames for centuries, but at last was compelled to purify its waters at a cost far exceedig the expense of preventing such contamination had the demands of competent judges been complied with a hundred years ago.

If New York and New Jersey should now initiate the plan above outlined the mistakes of other great municipalities could be happily avoided.

109 APPENDIX 6.

Legal Opinion.

By Attorney-General John Cunneen.

To the New York Bay Pollution Commission:

I note that you submit for my consideration the following inquiries:

"(1.) What is the status of the waters of New York harbor as to control over pollution by the federal Government and by the two States of New York and New Jersey?

"(2.) Whether the federal government would have jurisdiction over any phase of construction and operation of a large proposed trunk sewer to empty into the waters of New York harbor?

"(3.) What power, if any, has the State of New York to impose conditions upon the State of New Jersey as to constructing the proposed sewer and operating it in future?

"(4.) Whether the New York Bay Pollution Commission is authorized by law to suggest detailed plans for changes in construction of the New Jersey Sewer if same is to discharge into the waters of New York bay, and objection be made to the present plans as formulated by the New Jersey Commission?

"(5.) Whether in the event this commission finds it desirable to recommend for future consideration the establishment of a metropolitan sewerage district, covering parts of the two States of New York and New Jersey, the Legislatures of the two States have authority to establish such a district and appoint a commission having adequate powers of administration?"

(1.) In response to your query No. 1, I beg to call your attention to the provisions of a treaty entered into between the States of New York and New Jersey in the year 1833, and subsequently ratified by the Legislatures of both States and approved by Congress.

The first article of this treaty reads as follows:

110 "Article 1. The boundary line between the two States of New York and New Jersey from a point in the middle of Hudson river opposite the point on the west shore thereof, in the forty-first degree of north latitude, as heretofore ascertained and marked to the main sea, shall be the middle of the said river, of the bay of New York, of the waters between Staten Island and New Jersey, and of Raritan bay to the main sea, except as hereinafter otherwise particularly mentioned."

Among the exceptions is the following, contained in Article III. of said treaty:

"The State of New York shall have and enjoy exclusive jurisdiction of and over all the waters of the bay of New York, and of and over all the waters of Hudson river, lying west of Manhattan Island and to the south of the mouth of Spuyten Duyvil creek, and of and over the lands covered by the said waters to low water mark on the westerly or New Jersey side thereof, subject to the following rights of property and of jurisdiction of the State of New Jersey."

The treaty then proceeds to reserve to the State of New Jersey the exclusive right of property in and to the land under the water lying west of the middle of the bay of New York, and west of the middle of that part of the Hudson river which lies between Manhattan Island and New Jersey, and the exclusive jurisdiction of and over the wharves, docks and improvements made and to be made on the shore of said State, and of and over vessels aground on said shore, or fastened to any such wharf or dock, except that the said vessels shall be subject to the quarantine or health laws and laws in relation to passengers of the State of New York, which now exist or which may hereafter be passed. The right of regulating the fisheries is also reserved exclusively to the State of New Jersey on the westerly side of the middle of said waters.

The case of the People of the State of New York against Central Railroad Company of New Jersey, reported in 42 N. Y., at page 283,

111 reviews at some length the question of the rights of the two States in the waters of the Hudson river south of Spuyten Duyvil creek and west of the center of such river.

This was an action brought by the Attorney-General of the State of New York to abate as nuisances and cause the removal of certain wharves, piers and other erections extending into the harbor and river from the Jersey shore a distance of about a mile. The Court, per Smith, justice, in speaking of the provisions of Article III., which are above quoted, giving the State of New York exclusive jurisdiction over the waters of New York bay, and the Hudson river lying west of Manhattan Island and south of Spuyten Duyvil creek, and of the lands under such waters, says:

"This provision in the treaty most clearly and distinctly gives

and grants to, and vests in the State of New York, full, complete and undoubted control, government and jurisdiction of and over all the waters therein mentioned. Such was the clear intent and purpose of this provision; and so far as it was essential to the proper exercise of such jurisdiction, it gives a control also of and over the land covered by such waters. It doubtless was designed in the clause of said provision in these words: 'Of and over the lands covered by the said waters to low water mark,' to disembarrass the jurisdiction so conferred over the said water, from all pretense of right to interfere therewith arising from the legal maxim, that the owner of the soil owned all above it, cujus est solum, ajus est usque ad coelum.' So that the jurisdiction over the water should be absolute and unquestioned for all practical purposes."

The Court then goes on to point out that the rights over the water so granted to the State of New York were subject to the rights of property and of jurisdiction of the State of New Jersey, and after reviewing the several clauses of the treaty bearing on the jurisdiction of the two States within the waters in question, the following rule was deduced as to the character of the jurisidction of the State of New York:

112 "It was to be a police jurisdiction of and over all vessels, ships, boats or craft of every kind that did or might float upon the surface of said waters, and over all the elements and agents or instruments of commerce, while the same were afloat in or upon the waters of said bay and river for quarantine and health purposes, and to secure the observance of all the rules and regulations for the protection of passengers and property, and all fit governmental control designed to secure the interests of trade and commerce in said port of New York, and preserve thereupon the public peace.

"By this exception, it was designed that vessels afloat upon said bay and river should not escape or evade the quarantine laws, and the laws relating to passengers of New York, by coming to anchor on or near the New Jersey shore, or by becoming attached to the wharves or docks on said shore or adjacent thereto, but in all other particulars they were left subject to the laws of New Jersey."

And again the Court says:

"These articles, I think, properly interpreted, concur in showing that it was the intention of this treaty that both States should retain the absolute control of and over its own soil, and over anything annexed or attached to it, and over every ship, vessel, or other floating craft attached to any wharf or pier, or located in any dock upon its shore, or aground in the waters adjoining its shore, and of and over all persons living or being upon such wharves or vessels, and the property therein; and that each State intended to throw the shield of its State law, and State sovereignty, over all such ships, vessels, persons or property.

"A crime committed upon any vessel fastened to any wharf on the shore, or upon any vessel aground in the waters adjoining the shore of New Jersey, and west of the center of said river or bay, except those offenses specified in the said third article against the

quarantine or health laws, and the laws in relation to passengers of New York, would be, I think, clearly an offense against the peace and dignity of New Jersey, cognizable exclusively in her courts."

It was accordingly held in this case that the Courts of this State had no jurisdiction to restrain the erection or order the removal of the structures complained of.

113 It has, however, been since held, in the case of Ferguson vs. Ross, 126 N. Y., 459, that an action to recover a penalty for an alleged violation of the provisions of chapter 414 of the Laws of 1885, amending chapter 604 of the Laws of 1875, prohibiting the deposit of any material dredged or excavated from a slip, basin or other place in the North or East rivers, or in the bay of New York, within the jurisdiction of the State of New York, might be recovered in an action in the Courts of this State, where such dredgings were deposited in the waters west of the center of the Hudson river and south of Spuyten Duyvil creek, and the right of the State of New York to pass a law imposing such a penalty was upheld.

From a persual of these two cases, it will be seen that the jurisdiction of the State of New York in and to all the waters of the Hudson river and New York bay is primarily a police jurisdiction river and south of Spuyten Duyvil creek, and the right of the State of New Jersey to erect wharves, piers, bulkheads and improvements from its shores into such waters is specifically upheld in the Central Railroad case, from which I have above quoted.

Over and above the rights of the two contiguous States is the right of the federal government in the navigable waters of New York bay and the Hudson river, in so far as the protection of navigation is concerned. (See State of Pennsylvania vs. Wheeling Bridge Company, et al., 13 Howard, 518.)

(2.) In response to the second inquiry, as to "Whether the federal government would have jurisdiction over any phase of construction and operation of a large proposed trunk sewer to empty into the waters of New York harbor," I beg to call your attention to the facts relative to such sewer in the particular case under consideration.

114 In 1902 the Legislature of New Jersey established what was known as the Passaic Valley Sewerage District, which embraced a large number of municipalities and parts of municipalities in the counties of Passaic, Bergen, Hudson and Essex, and at a special session of the Legislature of 1903, an act was passed to relieve from pollution the rivers and streams within such Passaic Valley Sewerage District, and providing for the raising, collecting and expenditure of the necessary moneys.

The plans of the commission appointed under these acts provide for the emptying of the sewage from the district in question, which is estimated to contain nearly one million and five hundred thousand inhabitants, into the waters of New York bay near Bedloes Island on the New Jersey side of the State line, as defined in Article III, of the treaty hereinbefore quoted from.

No facts have been submitted as to whether or not the construction of the proposed sewer and its operation would, as matter of

fact, interfere with the navigation of the Hudson river and New York bay. If there is any such interference, I am of the opinion that the federal government might and would interpose and assert its rights to free such river or harbor from such obstruction or interference with navigation.

As to the jurisdiction of the federal government in the matter, it would seem to me that under the authority of the State of Missouri vs. State of Illinois, and the Sanitary District of Chicago, the Supreme Court of the United States would have original jurisdiction in any proceeding which might be instituted by the State of New York to restrain the construction or operation of the proposed sewer.

The case above mentioned arose in regard to the construction and operation of the so-called Chicago Drainage canal, whereby
115 the sewage from the city of Chicago was, through the intermediate channels of the Drainage canal and the Illinois river, emptied into the Mississippi river, which at that point runs between the States of Illinois and Missouri.

The State of Missouri sought in the Supreme Court of the United States to restrain the emptying of such sewage into the Mississippi river. The bill in the action was demurred to, but the Court sustained the right of the State of Missouri to maintain its proceeding. The Court said:

"An inspection of the bill discloses that the nature of the inquiry complained of is such that an adequate remedy can only be found in this Court at the suit of the State of Missouri. It is true that no question of boundary is involved, nor of direct property rights belonging to the complainant State. But it must be surely conceded that, if the health and comfort of the inhabitants of a State are threatened, the State is the proper party to represent and defend them. If Missouri were an independent and sovereign State all must admit that she could seek a remedy by negotiation, and, that failing, by force. Diplomatic powers and the right to make war having been surrendered to the general government, it was to be expected that upon the latter would be devolved the duty of providing a remedy, and that remedy, we think, is found in the constitutional provisions we are considering.

"The allegations of the bill plainly present such a case. The health and comfort of the large communities inhabiting those parts of the State situated on the Mississippi river are not alone concerned, but contagious and typhoidal diseases introduced in the river communities may spread themselves throughout the territory of the State. Moreover, substantial impairment and prosperity of the towns and cities of the State situated on the Mississippi river, including its commercial metropolis, would injuriously affect the entire State."

The above reason would apply with equal force to the case under consideration. The sewage from territory inhabited by a million
116 and a half of people, cast into the waters of New York harbor, in addition to the sewage already emptied into those waters, might easily create a condition which would injure the health

of the great city of New York, which is the metropolis not only of the State, but of the country.

It is, therefore, quite clear to my mind that should such a condition arise, the State of New York would be authorized to begin proceedings in the Supreme Court of the United States to compel the State of New Jersey and the Passaic Valley Sewerage District to refrain from polluting the waters of New York harbor with this great mass of sewage.

(3.) In response to your third inquiry, I beg to inform you that while the State of New York can, of course, enter into any negotiations it sees fit with the State of New Jersey, yet it cannot impose and enforce any conditions in reference to the construction and operation of such sewer, upon the Passaic Valley Sewerage District or the State of New Jersey, which would be enforcible in any other way than by a proceeding in the United States Supreme Court, to restrain the use and operation of such sewer. In other words, while under the authority of Ferguson vs. Ross, above cited, the State of New York might pass a law prescribing a penalty for dumping sewage in the waters of New York harbor or the Hudson river as far west as low water mark on the New Jersey shore, yet I am of the opinion that such a penalty could not be enforced or collected as against the State of New Jersey or the Passaic Valley Sewerage District, in the Courts of this State, and that, therefore, the proper forum from which to seek redress would be the United States Supreme Court.

(4.) In response to your fourth inquiry, I beg to call your attention to the statute creating the investigating commission of this State. Section two thereof provides as follows:

117 "Such commission shall confer with the authorities of the State of New Jersey, take the testimony of witnesses, if necessary, and otherwise make such investigations as it may deem advisable, to determine the character of such threatened pollution, if any, and the means necessary to effectually prevent the same, in order to protect the health of the people of this State."

In view of the fact that the State of New Jersey would in no way be bound to act upon any specific recommendations or suggestions of detailed plans for changes of the construction of the sewer in question, I see no reason why your commission might not submit such suggestions and recommendations, if it saw fit, the same as it might submit the same at any oral conference had under the provisions of the sections above quoted with the authorities of the State of New Jersey.

(5.) As to the fifth and last inquiry, I am of the opinion that the States of New York and New Jersey may, if they see fit, construct a metropolitan sewerage district, covering parts of the territory of the two States, and giving jurisdiction thereover to the Courts of one of the other of said two States, as to all matters pertaining to the proper sewerage of said district. Such concurrent acts of the States of New York and New Jersey should, however, in my judgment, be approved and ratified by an act of Congress, for the reasons hereinbefore set forth, namely, that the federal government

has supreme control over the navigable waters of the Hudson river and New York bay, and its approval should therefore be had to the joint action of the contiguous States.

As to the power of the Attorney-General to proceed against the State of New Jersey and the Passaic Valley Sewerage District to restrain the construction or operation of the proposed sewer, I am of the opinion that section 52 of the Executive law, which
118 gives to the Attorney-General power to "prosecute and defend all actions and proceedings in which the State is interested," is broad enough in its terms to include the authority to begin such restraining action. In support of this theory, it will be noted the right of the Attorney-General to begin a similar action does not seem to have been questioned in the case of the People vs. The Central Railroad of New Jersey, hereinbefore quoted from, and the case of Missouri vs. Illinois specifically holds that the pollution of a navigable stream is a matter in which the State is interested, and therefore a proper one for its legal representatives to act in behalf of the State.

119 APPENDIX 7.

New York Law—Authorizing Appointment of Commission.

General—All Counties.

Laws of New York—By Authority.

(Every law, unless a different time shall be prescribed therein, shall not take effect until the twentieth day after it shall become a law. Section 43, article II, chapter 8, General Laws.

Chapter 539.

An Act to authorize the appointment by the Governor of a commission to investigate certain threatened pollution of the waters of New York bay, and making an appropriation for the expenses of such commission.

Became a law, May 11, 1903, with the approval of the Governor. Passed, three-fifths being present.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

Section 1. The Governor is hereby authorized to appoint a commission, consisting of five members, to investigate the alleged contemplated construction of a sewer or sewers in the State of New Jersey and the discharge therefrom of sewage into the waters of New York bay. The members of such commission shall receive no compensation for their services, but shall be entitled to their actual necessary traveling and other expenses incurred in the performance of

their duties. Such commission shall organize by the selection of one of its members as chairman and another as secretary.

120 §2. Such commission shall confer with the authorities of the State of New Jersey, take the testimony of witnesses, if necessary, and otherwise make such investigations as it may deem advisible to determine the character of such threatened pollution, if any, and the means necessary to effectually prevent the same, in order to protect the health of the people of this State.

§3. Each member of such commission shall have the power to administer oaths, and the commission shall have power to subpœna witnesses and take testimony, and in addition shall have all the powers of legislative committees as provided by article three of the Legislative Law. On or before February first, nineteen hundred and four, the commission shall report to the Governor the result of its investigation, together with such recommendations as to needed legislation or other action on the part of the State to prevent the pollution of the waters of New York bay from the causes specified in this act, as it may deem advisable.

§4. The sum of two thousand dollars, or so much thereof as may be necessary, is hereby appropriated out of any moneys in the treasury, not otherwise appropriated, for the purposes of this act, to be paid by the treasurer on the warrant of the comptroller, on the order of the chairman of such commission.

§5. This act shall take effect immediately.

STATE OF NEW YORK,
Office of the Secretary of State, ss:

I have compared the preceding with the original law on file in this office, and do hereby certify that the same is a correct transcript therefrom and of the whole of said original law.

JOHN F. O'BRIEN,
Secretary of State.

121 APPENDIX 8.

An Act to Provide for the Appointment of a Metropolitan Sewerage Commission and Making an Appropriation Therefor.

The people of the State of New York, represented in Senate and Assembly, do enact as follows:

Section 1. The Governor is hereby authorized to appoint within thirty days after the passage of this act five citizens of the State, two at least of whom shall be residents of the city of New York, who together with the State Engineer and Surveyor, the State Attorney-General and the Mayor of the city of New York shall constitute a temporary commission to be known as the New York Metropolitan Sewerage Commission. One at least of the five citizen members should be a lawyer and two at least should be civil engineers.

§2. The duties of this commission shall be to continue the work of the New York Bay Pollution Commission established by chap-

ter five hundred and thirty-nine of the Laws of nineteen hundred and three and to extend the work of this commission so as to include the following duties:

(1.) To make further investigations into the present and probable future condition of the purity and pollution of the waters of New York bay, and of the rivers and other bodies of water tributary thereto and adjacent to the several boroughs of New York city and its neighboring districts.

(2.) To consider and investigate the present conditions and the future needs for sewerage and sewage disposal in New York
122 city and in the adjoining municipalities and neighboring districts.

(3.) To cooperate with any duly authorized body or commission having similar authority from the State of New Jersey, in the joint consideration of the most effective, efficient and feasible means of permanently improving and protecting the purity of the waters of New York bay and of the rivers and other bodies of water tributary and adjacent thereto, making, in addition to other inquiries, examinations, investigations and surveys to determine the best plan for the final disposal of the sewage of the entire metropolitan district lying in both States, either by discharging or pumping the same through large outlet sewers or tunnels out to sea, or by other means; and also giving particular consideration to the best system of administrative control for the inception, execution and operation of such plans for ultimate sewage disposal by a separate and distinct sewerage district and a permanent commission in each State, or by one interstate metropolitan sewerage district and commission to be established by an agreement between the two States; if necessary, to be ratified by Congress, or by other means.

(4.) To submit to the Legislature in writing on or before February first, nineteen hundred and eight, a full and complete report of its investigations, surveys and estimates of cost of the several plans deemed worthy of especial consideration. Also to submit such definite conclusions and recommendations as may have been reached conjointly by the Metropolitan Sewerage Commission herein established acting in conjunction with any similar body appointed by the State of New Jersey, relating to the most effective, efficient and feasible means or plan of permanently improving and protecting the purity of the waters of New York bay and of the rivers and other
123 bodies of water tributary and adjacent thereto, as well as a definite scheme for the administration of the inception, execution, permanent operation and government of such means or plan of improvement and protection.

§3. The members of the New York Metropolitan Sewerage Commission herein provided for, shall before entering upon the discharge of their duties take and subscribe the constitutional oath of office and file the same with the Secretary of State. They shall within twenty days after appointment, and at the call of the State Engineer, meet at the office of the latter in Albany and shall organize by the selection of one of the members to be chairman of the commission and another to be its secretary.

The commission may engage such engineering, legal, and other expert services and advice, and such clerical, stenographic and other assistance as it may deem necessary for the prosecution of its duties.

§4. Each member of the commission shall have the power to administer oaths, and the commission shall have the power to subpœna witnesses and take testimony, and in addition shall have all the powers of legislative committees as provided by article three of the Legislative Law. The members of the commission and all persons duly authorized by the commission shall have the right of entry and passage to any place or property for the purpose of making surveys or examinations.

§5. The commission shall terminate on February 1, 1908, and all maps, results or surveys and examinations, estimates and other papers and matter acquired by the commission shall be properly indexed and labelled and turned over to the State Engineer and Surveyor.

124 §6. The members of the commission shall receive no salary but shall be paid their reasonable and necessary expenses actually incurred in the prosecution of their duties, and the five citizen members shall be each paid a just and reasonable per diem compensation, to be determined by the Governor, for the time actually and necessarily employed on the work of the commission.

§7. The sum of fifteen thousand dollars, or so much thereof as may be necessary, is hereby appropriated out of any money in the treasury not otherwise appropriated, for the purposes of this act, to be paid by the State Treasurer on the warrant of the Comptroller on the order of the chairman of the commission.

§8. The Secretary of State is hereby authorized and requested to communicate with the Governor of the State of New Jersey, transmitting with the Governor of the State of New Jersey, transmitting a copy of this act and to extend through him an invitation to the State of New Jersey to cooperate with the State of New York in the carrying out of the purposes to be attained by this act and to appoint a commission to represent the State of New Jersey and unite with the New York commission authorized by this act in the investigations, surveys, conclusions and recommendations herein provided, it being desired that, if possible, the two commissions may reach similar conclusions and agree on a common plan for the accomplishment of the purposes to be attained by this act, and that they may submit identical or similar reports and recommendations to their respective legislatures.

§9. This act shall take effect immediately.

125 APPENDIX 9.

List of Meetings Held by the Commission and Special Features Considered Thereat.

June 30, 1903—All members of the commission present (five).
Meeting held on board New York State Board of Health Steamer "Governor R. P. Flower."
Inspection of New York harbor; organization of commission; Dr. Daniel Lewis, chairman; Louis L. Tribus, secretary. Assignment of subjects to members of commission for special individual investigation.
November 30, 1903—Four members of the commission present.
Meeting held in New York city.
Consideration of important details of New Jersey project; authorization given for special trips of investigation of sewage disposal systems.
December 22, 1903—All members of the commission present.
Meeting held in office of the President of the Borough of Richmond, New Brighton, S. I.
Public hearing and testimony, taken under oath, of pilots, etc., as to tidal currents, and discussion of shellfish industries and location of beds.
January 22, 1904—All members of the commission present.
Joint session of New York Commission and Passaic Valley District Sewerage Commission.
126 Meeting held in New York city.
General and free discussion of New Jersey project.
February 5, 1904—All members of the commission present.
Meeting held in office of the State Commissioner of Health at Albany.
Discussion of proposed report and topics to be considered therein. Consultation with Deputy Attorney-General upon legal questions involved in report.
February 12, 1904—All members of the commission present.
Joint session of New York Commission and Passaic Valley District Sewerage Commission.
Meeting held in office of the latter in Newark, N. J.
General discussion of details of New Jersey project and hearing of arguments of the engineers of the Passaic Valley Commission in answer to written questions previously presented by the New York Commission.
February 10, 1905—All members of the commission present.
Meeting held in New York city.
Discussion of individual reports presented by members of the commission upon their special investigations to date. Selection of features for final report, and general form of recommendations to be incorporated in a legislative bill.
March 10, 1905—All members of the commission present.
Meeting held in New York city.

Discussion of draft of final report as prepared by the Secretary.

The Secretary authorized to complete same with amendments
127 as suggested, and with the chairman to present it personally to the Governor at the earliest feasible date. To have report printed as soon as possible thereafter, for general distribution.

128 APPENDIX 10.

Financial Statement.

Appropriation				$2,000 00
Disbursements:				
1903.				
Oct. 15.	Evening Union Co., stationery and printing.	$12 65		
Dec. 10.	Louis L. Tribus, Secretary, traveling, postage and typewriting.	41 05		
March 14.	Louis L. Tribus, Secretary, traveling, postage and typewriting.	67 71		
	John P. Martin traveling and stenographic service	356 37		
May 26.	Daniel Lewis, traveling expense	48 75		
July 26.	Louis L. Tribus, Secretary draft of map and typewriting	90 16		
	Olin H. Landreth, traveling and typewriting	123 54		
			$740 23	
Accounts due:				
1905.				
	George A. Soper, traveling and analyses	$484 40		
129	Myron S. Falk, traveling and typewriting	13 94		
	Olin H. Landreth, traveling and typewriting	36 18		
	Louis L. Tribus, Secretary, traveling, map exhibit, report binders and typewriting	246 60		
			781 12	
				$1,521 35
Balance towards final petty expenses and publication of report				$478 65

130 APPENDIX 11.

Names of Those Rendering Special Assistance to Commission.

Bauer, Jacob L., Civil Engineer, Elizabeth, N. J.
Bender Hygienic Laboratory, Albany, N. Y.
Bridgman, Edw. C., Map Publisher, New York.
Brown, Wm. M., Chief Engineer Metropolitan Sewerage Commission, Boston, Mass.
Cantor, Jacob A., President Borough of Manhattan, New York.
Cassidy, Joseph, President Borough of Queens, New York.
Church, Sanford T., Deputy Attorney-General, Albany, N. Y.
Cooper, Sam'l L., Commissioner Public Works, Yonkers, N. Y.
Cromwell, George, President Borough of Richmond, New York.
Cunneen, John, Attorney-General, Albany, N. Y.
Fetherston, John T., Civil Engineer, New Brighton, N. Y.
Forest, Fish and Game Commission, Albany, N. Y.
Freeman, L. W., Civil Engineer, Mariners Harbor, N. Y.
Glorieux, Wm. L., President South Orange, etc., Joint Sewer Commission, Irvington, N. J.
Grabkowitz, J. M., Draughtsman, New Brighton, N. Y.
Grunenthal, A. F., Draughtsman, New Brighton, N. Y.
Haffen, Louis F., President Borough of The Bronx, New York.
Harrison, E. W., Civil Engineer, Jersey City, N. J.
Hommann, C. C., Civil Engineer, Perth Amboy, N. J.
Housman, Jacob, Oyster Dealer, Mariners Harbor, N. Y.
Jackson, Daniel D., Chemist, Brooklyn, N. Y.
Kohler, Capt. C. H., Superintendent Staten Island Rapid Transit Ferry Company, New Brighton, N. Y.
131 Lennon, John J., Stenographer, New Brighton, N. Y.
Livingston, George, Commissioner of Public Works, Borough of Manhattan, New York.
Loomis, Horace, Chief Engineer Sewers, Borough of Manhattan, New York.
Luster, W. H., Jr., Civil Engineer, Elizabeth, N. J.
Mackenzie, Gen. A., Acting Chief of Engineers, U. S. Army, Washington, D. C.
Marshall, Chas. A., Secretary to the Commissioner of Public Works, Borough of Richmond, New York.
Marshall, Lieut.-Col. W. L., U. S. Engineer Corps, New York.
Martin, John P., Court Stenographer, New York.
Massa, Chas. G., Civil Engineer, Fort Lee, N. J.
Muirhead, Chas. H., Mayor, South Orange, N. J.
McCann, Thos. H., Civil Engineer, Hoboken, N. J.
Musgrave, Francis W., Stenographer, New Brighton, N. Y.
Oxholm, Theodor S., Civil Engineer, West New Brighton, N. Y.
Pearce, Dr. R. M., Director of Bender Laboratory, Albany, N. Y.
Potter, Alexander, Civil Engineer, New York.
Raymond, Lieut.-Col. C. W., U. S. Engineer Corps, New York.
Redfield, Wm. C., Commissioner of Public Works, Borough of Brooklyn, New York.

Ryan, P. J., Mayor, Elizabeth, N. J.

Seehusen, Ernest H., Superintendent Bureau of Sewers, Borough of Richmond, New York.

Silva, J. J., Quarter-master Staten Island Rapid Transit Ferry Company, New Brighton, N. Y.

Stickney, Col. Amos, U. S. Engineer Corps, New York.

Suter, Col. Chas. R., U. S. Engineer Corps, New York.

132 Swanstrom, J. Edward, President Borough of Brooklyn, New York.

Thatcher, John, Superintendent Bureau of Sewers, Borough of Brooklyn, New York.

United States Census Bureau, Washington, D. C.

United States Commission of Fish and Fisheries, Washington, D. C.

United States Steamboat Inspection Service, New York.

Van Pelt, Capt. F. P., Superintendent New York, New Jersey and Sandy Hook Pilots' Association, New York.

Whittemore, Walter F., Civil Engineer, Hoboken, N. J.

Wyeth, Charles, New York State Surveyor of Oyster Lands, New York.

STATE OF NEW YORK:

Report of the New York Bay Pollution Commission to Hon. Frank Wayland Higgins, Governor, April 30, 1906.

Commissioners: Daniel Lewis, Chairman, Olin H. Landreth, Myron S. Falk, George A. Soper, Louis L. Tribus, Secretary.

Transmitted to the Legislature May 3, 1906.

(Here insert map marked page 1 Exhibit No. 3.)

2 STATE OF NEW YORK:

Report of the New York Bay Pollution Commission to Hon. Frank Wayland Higgins, Governor, April 30, 1906.

Commissioners: Daniel Lewis, Chairman; Olin H. Landreth, Myron S. Falk, George A. Soper; Louis L. Tribus, Secretary.

Transmitted to the Legislature May 3, 1906.

3 STATE OF NEW YORK:

No. 76.

In Assembly, May 3, 1906.

Second and Final Report of the New York Bay Pollution Commission to Frank Wayland Higgins, Governor of the State.

STATE OF NEW YORK:

EXECUTIVE CHAMBER,
ALBANY, May 3, 1906.

To the Legislature:

I herewith submit the report of the New York Bay Pollution Commission.

FRANK W. HIGGINS.

NEW YORK, April 30, 1906.

Hon. Frank Wayland Higgins, Governor, State of New York, Albany, N. Y.:

SIR: Under date March 31, 1905, the New York Bay Pollution Commission presented to you its report of investigations
4 carried on during the two preceding years concerning the condition of the waters of New York Bay and vicinity, and making certain recommendations. As the presentation of our report was unavoidably delayed until nearly the close of the legislative session; acting on your suggestion, the Legislature continued the life of the commission for another year, and made a small appropriation for its expenses, rather than at that late date taking up the question of authorizing the appointment of a new commission with broader powers, and an appropriation sufficient to carry on much further the work begun. With the small sum of money at its command, the commission has been unable to do other than continue in a small way some of the examinations which it felt to be most essential, namely, bacteriological and sanitary examinations of the waters and shores of the harbor. The accompanying report of the sub-committee (Appendix) confirms quite strikingly the conclusions arrived at by the earlier investigations, as reported upon last year, demon-

strating still more clearly the need for full study and the earliest possible consideration of the whole question of preventing the further pollution of the waters in question and the ultimate doing away with even the present causes of contamination.

Certain objections had been made to the form of the bill which the commission suggested a year ago, so that a new measure has been under consideration for this year's action, similar in its general purport but differing in some special details.

The technical journals and the daily press of New York city have given much publicity to the matters reported upon, and commend very fully the work already done and that proposed for the future. The Chamber of Commerce of the State of New York, the Merchants' Association of New York, the Board of Trade
7 & 6 and Transportation, the Maritime Association of the Port of New York, the New York Produce Exchange, the City Club, the American Scenic and Historic Preservation Society, the Municipal Engineers of New York City, and other representative bodies have given evidences of being very much alive to the necessity of the case.

The status of the New Jersey legislation remains unchanged since our last report, except that a special session of the New Jersey Legislature is likely to be called in September to consider the subject very fully.

There has been so great an interest taken in this matter, that the commission would ask for the printing of an additional edition of its former report, the present one having long since become practically exhausted. It would seem desirable to have such edition made an appendix of this report, so that all those interested in the subject may readily compare this year's results with those formerly presented.

Respectfully submitted,

NEW YORK BAY POLLUTION COMMISSION.
DANIEL LEWIS *Chairman*.
OLIN H. LANDRETH.
GEORGE A. SOPER.
MYRON S. FALK.
LOUIS L. TRIBUS, *Secretary*.

Report on the Sanitary Conditions of New York Bay as Shown by Chemical and Bacteriological Analyses of the Waters and Inspections of the Shores.

By George A. Soper, Special Committee, April 30, 1906.

9 The Sanitary Condition of New York Bay as Shown by Chemical and Bacteriological Analyses of the Waters and Inspections of the Shores.

By Commissioner George A. Soper.

The sanitary examinations of the waters of New York Bay and vicinity recorded in the first report of the New York Bay Pollution Commission, made May 1, 1905, have since been continued and extended. The conclusions hitherto reached have been, for the most part, fully confirmed by the studies of the last year.

Before undertaking to consider the most recent work of the commission, the more essential of the conclusions already reached may be repeated:

(1.) The effects of the present pollution of New York Bay, although not great, are nevertheless measurable.

(2.) A careful study of the water in the bay and rivers about New York shows that the sewage of New York City is not promptly flushed out to sea, except during freshets in the Hudson.

(3.) It is probable that most of the sewage which enters the bay is disposed of in the bay by animals and plants, chiefly the bacteria which live in this water.

(4.) The drainage which now enters the bay does so in the most favorable manner possible for diffusion; that is, from a large number of outlets situated along an extensive shore line.

10 (5.) How much sewage and other organic matter can be emptied into the bay without killing those forms of life which now destroy the sewage and so creating a general nuisance, it is impossible to say. This is a matter of great importance, but its proper study requires analyses and experiments which have been beyond the reach of this commission.

(6.) Compared with fresh water streams or the ocean, New York Bay is not a favorable place for the inoffensive disposal of sewage.

(7.) Should the bay become overloaded with sewage, the odors which would arise from it would be particularly offensive.

(8.) The total amount of solid matter which now enters the bay with house and street sewage every twenty-four hours is approximately equivalent to 1,047 tons of dry sludge. About one-half of this is organic matter.

(9.) Long before a general nuisance is produced, local nuisances will occur, as may be seen at present where sewage and drainage

COPY BOUND

from industrial works empty into still, or comparatively still water in this vicinity.

(10.) The oyster beds in New York Bay are almost exclusively located on the southeast side of Staten Island and Gravesend Bay, beyond the Narrows.

(11.) Most of the oyster and clam beds are now free from dangerous pollution, although there are some on the Staten Island shore near the Narrows and the Kill von Kull, and some in Gravesend Bay, which are nearer sewer outfalls than is proper.

(12.) The increasing amount of pollution to which the waters of New York Bay are subject makes it seem only a question of time when oyster culture will be driven from this locality; but
11 with wise and careful protection, a large part of the present oyster grounds can be kept safe for some years to come.

(13.) The almost universal custom in this vicinity of "drinking," that is, bleaching and bloating oysters in polluted streams of fresh water, places all shellfish under suspicion of being contaminated.

(14.) The pollution of the bay has had no visible effect upon the number of fish caught in the vicinity of New York, although petroleum and other industrial wastes appear to have occasionally affected the flavor, and consequently the value, of small catches of shad.

(15.) The natural increase in population of New York and vicinity will, by 1930, probably increase the present amount of pollution about 65 per cent.

The principal points of information sought in the recent work of the commission have been—(1) To determine whether the waters of New York Bay were comparatively uniform in quality at all depths, or whether a perfect mixture of the salt water, fresh water and sewage which entered it did not occur; (2) Whether the waters of the East River, Harlem River and Hudson River bore positive evidence of pollution; (3) Whether the supply of oxygen was always sufficient for the oxidation of the organic matter by the bacteria.

The analyses have been confined to chemical and bacteriological determinations uniform in character with those recorded in the first report of the commission. The methods of analysis and the ways of expressing the results have been the same. There have been one hundred and fifteen chemical analyses and the same
12 number of bacteriological examinations. As a rule, samples for chemical and bacteriological analyses were collected simultaneously. The total number of analyses was very small, considering the size of the problem to be studied.

The great extent of the harbor and its tributaries and the multiplicity of the conditions of pollution and purification which called for investigation needed far more extensive analytical studies than the slender means of the commission permitted. The analytic work done thus far should be regarded only as an indication of the great value and meaning which would attach to similar work if carried out on a large scale.

CLOSE IN CENTER

It is hoped, if further studies are to be made of the conditions of these waters, that opportunities will be afforded for keeping the harbor and adjacent waters under adequate observation for at least one full year. Facilities should be provided for the collection and analysis of several thousand samples.

The numbers of bacteria found were, in most cases, smaller than would be expected from the results of analyses published by the commission in its first report. The numbers would have been larger had the observations been made in the summer season, for cold exercises a restraining action on the growth and multiplication of bacteria.

A sanitary inspection of the shores of the bay was made in order to discover, if possible, whether any visble evidence of pollution by sewage, garbage or other refuse existed there. This inspection yielded unexpectedly interesting and instructive results.

13 A—Results of Bacteriological Analyses.

Analyses were made to determine the numbers of bacteria in the waters and, to some extent, their kind. The principal kind looked for was B. coli, an invariable accompaniment of sewage. The examinations for B. coli were made by the "presumptive test," already described in the first report of the New York Bay Pollution Commission, and checked by means of a special method which has come into regular use at the Mount Prospect laboratory, Brooklyn, N. Y. This method has not yet been published and cannot, consequently, be fully described here. It will be known as the "bile lactose method" and was devised by Mr. D. D. Jackson into whose hands the actual work of the bacteriological and chemical analyses for the commission has been intrusted. ,

1. Bacteria at Different Depths in Upper New York Bay.

Samples of water were taken for analysis at different depths in upper New York Bay to determine whether there was an appreciable difference in the bacterial condition of the water at the surface and at different points toward the bottom. The results are given in tables 1 and 2.

Table 1. Results of bacterial analyses of water taken from various points at different depths in Upper New York Bay. The samples were collected from a boat on January 28, 1906, between 10:00 a. m. and 3:30 p. m. At Governors Island the tide was high at 10:40 a. m. and low at 5:12 p. m. The wind was north to northwest, with a minimum velocity of 4 miles per hour between noon and 1:00 p. m. and 13 miles per hour between 3:00 and 4:00 p. m.

D CLOSE IN CENTER

15 Tables 1 and 2 show that the numbers of bacteria were very much larger near the surface than in the water below. The reduction in the numbers with the depth is striking and indicates that most of the sewage, and other decomposable refuse with which the bacteria were associated, was flowing around at the surface and not mixing uniformly with the water. The tests for B. coli confirm the conclusions which might be derived from a study of the numbers of bacteria alone. There were more coli at the top of the water than in the water below.

In a very large majority of all the samples examined in the commission's investigations, the presumptive tests for coli have resulted positively. In a few cases they have resulted negatively at depths of 60 feet and over.

2. Bacterial Condition of the Gowanus Canal.

One of the most polluted arms of the Upper Bay is the Gowanus Canal on the Brooklyn shore. The odors from this canal constitute such a decided nuisance to the people who live and work in its vicinity that the City of New York has recently let contracts for the construction of pumping engines and a tunnel at an expense of about $275,000 to flush out this odorous canal.

In order to obtain an accurate idea of the data which this water would yield on analysis, chemical and bacteriological examinations were made of three samples of the canal water taken from different points between the outlet and the head of the canal. The results are given in table 3.

Table 3. Results of chemical and bacterial analyses of water taken from the Gowanus Canal. The samples were taken from a boat at a depth of one foot below the surface on February 3, 1906.

16

Map No.	Point of collection of sample.	Free ammonia.	Albuminoid ammonia.	Chlorine.	Bacteria per c. c.	Tests for B. Coli. 0.1 c. c.	1.0 c. c.	10 c. c.
84	Head of Gowanus Canal.	24.00	5.40	1,400	1,050,000	+	+	+
85	Below Union Street.....	5.60	2.16	5,900	190,000	+	+	+
86	Near Outlet	3.40	1.26	7,450	100,000	+	+	+

According to this table, there was a decided difference between the condition of the water of the canal at different points, but in no case was it satisfactory from a sanitary standpoint. The bacteria were enormously large in number, as were the amounts of free and albuminoid ammonia present. The tests for coli resulted positively in every case.

The condition of the Gowanus Canal, as shown by this table, of Bodine Creek and of the Rahway River, as given in table 5, and of the Bronx River, as given in table 6, indicate conditions which should serve as a warning of what the whole bay may become if it is not protected against unlimited pollution in the future.

COPY BOUND

3. Bacteria at Different Depths in the Lower Bay and Narrows.

The bacterial condition of the water of the Lower Bay and Narrows at different depths was investigated to determine whether there was any marked difference in the pollution at points below the surface as compared with the conditions at the top. The results are given in table 4.

Table 4. Results of bacterial analyses of water taken from various points at different depths in the Lower Bay and Narrows. The samples were collected from a boat on February 17, 1906, between 2:45 p. m. and 4:40 p. m. High water occurred at Sandy
17 Hook at 2:39 p. m., and at Governor's Island at 2:55 p. m. The wind was southwest to south and averaged 6½ miles per hour.

Map No.	Point of collection of sample.	Time.	Depth below surface in feet.	Bacteria per c. c.	Tests for B. Coli. 0.1 c. c.	1.0 c. c.	10 c. c.

92	Narrows	4:10	80	460	0	+	+

18

Table 4 shows that the water near the surface contained several times as many bacteria as the water near the bottom. The numbers of bacteria were not quite as large in the Lower Bay as in the Upper Bay, but the difference was slight. Not so many samples of deep water as surface water gave positive results in the coli tests.

4. Bacteria in Upper Bay and Lower Parts of the East and North Rivers.

In order to obtain further information concerning the bacterial condition of the water in the Upper Bay and lower ends of the East and North rivers, a series of examinations of these waters was made as shown in table 5.

Table 5. Results of bacterial analyses of water taken from various points in the Upper Bay and lower ends of the East and North rivers. The samples were collected from a boat on March 2, 1906, between 11:00 a. m. and 5:15 p. m. At Governors Island high tide occurred at 12:20 p. m., and low tide at 7:10 p. m. The wind was east and northeast and ranged from 5 to 9 miles per hour.

136	Rahway River, N. J., over oyster beds	2:15	5,800	+	+	+

One of the most significant features of table 5 is the large proportion of positive results obtained in the tests for B. coli. Nearly every test resulted positively. The numbers of bacteria were comparatively large, in some cases decidely so. The greatest numbers were contained in samples taken within range of extensive local sources of pollution, such as the Gowanus Canal and the
19 large sewer which empties from the Brooklyn shore in the neighborhood of 65th street.

The East River contained many more bacteria than the North River or the Upper Bay—or even the Staten Island shore, which is one of the most polluted localities which have been investigated.

Samples of water were taken from Bodine Creek and the Rahway River, which latter empties into the Arthur Kill on the west side of Staten Island, in order to show the conditions of water in which oysters are extensively "drinked" in preparation for the New York market. Both streams were known from previous investigations to be decidely polluted with sewage. The conditions surrounding Bodine Creek were described in the first report of the New York Bay Pollution Commission. The Rahway River receives the sewage of the municipality of Cranford and the sewage of the city of Rahway.

The results of these examinations are given in table 5. In view of the known pollution of these two streams, it seems a little curious that the numbers of bacteria were not larger.

5. Bacterial Condition of the Lower Bronx River.

Notwithstanding the fact that some effort has been made to protect the lower part of the Bronx River against sewage pollution, the condition of that stream is far from satisfactory. Samples of water were taken at different points below the dam toward the mouth of the Bronx River with results which are given in table 6.

Table 6. Results of chemical and bacterial analyses of water taken from various points in the Bronx River at a depth of one foot below the surface. The samples were collected from a boat on March 31, 1906, between 3:00 and 4:30 p. m. High water occurred at
20 Willett's Point at 3:20 p. m. The wind was northwest and averaged 31 miles per hours. (Results stated in parts per million.)

140	Bronx River, off Hunts Point	.240	.260	13,500	3,400	+	+	+

NOTE.—The following figures give the number of cubic centimeters of dissolved oxygen per litre found in these samples: No. 137, 8.62 c. c. oxygen; No. 138, 9.28 c. c. oxygen; No. 139, 7.07 c. c. oxygen; No. 140, 9.61 c. c. oxygen.

The numbers of bacteria given in this table show diminishing pollution as the river approaches its mouth. From the dam to the mouth of the river the reduction in the numbers of bacteria was decided. The differences in the amounts of free and albuminoid ammonia were not so noticeable, but there was a progressive reduction in the free ammonia which confirms the bacterial results. It is interesting to note that all of the tests for B. coli gave positive results.

6. Bacteria in the Rivers Surrounding Manhattan Island.

A series of analyses was made to determine the bacterial condition of the Hudson, East and Harlem rivers. The results of these examinations are given in table 7.

Table 7. Results of bacterial analyses of water taken from various points in the waters surrounding Manhattan Island. The samples were collected from a boat on April 1, 1906, between 9:55 a. m. and 3:05 p. m., at a depth of one foot below the surface, unless otherwise indicated. High water occurred at Governors
21 Island at 12:30 p. m. The tide was low at Governors Island at 7:16 a. m., and at Willetts Point at 10:13 a. m. The wind was northwest and ranged from 17 to 32 miles per hour.

Nearly all of the samples recorded in the foregoing table gave positive results in the presumptive test for B. coli. The only exception was in water from the Harlem River. The condition of the Harlem appears to have been much better than either that of the East or Hudson River, although the numbers of bacteria were in no case low, considering the season of the year when the samples were collected. The East River was decidedly more polluted than either the Hudson or Harlem. The average of the numbers of bacteria was more than twice as high in the East River as in the other two rivers.

The water near the bottom of the East River near the Battery contained about as many bacteria as the water at the surface at this point.

22 The Hudson from its junction with the Harlem to 40th street was, like the East River, decidedly polluted.

B—Results of Chemical Analyses.

1. Chemical Condition of Water from Different Depths in the Upper Bay.

Samples of water from different depths at points between the Battery and the Narrows were analyzed chemically to determine whether the evidence so obtained would show any difference in the conditions. The results are given in tables 8 and 9.

Table 8. Results of chemical analyses of water taken from various points at different depths in Upper New York Bay. The samples were collected from a boat on January 28, 1906, between 10:00 a. m. and 3:30 p. m. At Governor's Island the tide was high at 10:40 a. m., and low at 5:12 p. m. The wind was north to northwest with a minimum velocity of 4 miles per hour between noon and 1:00 p. m., and 13 miles per hour between 3:00 and 4:00 p. m. (Results stated in parts per million).

The analyses recorded in these two tables show that there was a reduction in the amount of albuminoid and free ammonia in the water as the depth from the surface increased. In some cases this difference was very decided; in others it was less marked. An average of all the results indicates that the water near the surface was much more polluted than the water below.

It is interesting to observe in this table that the chlorine invariably increased with the depth, showing that there was a larger percentage of sea water at the bottom than at the surface. Reasons for believing that this was the case were given in the first report of the New York Bay Pollution Commission.

2. Chemical Condition of the Water at Different Depths in the Lower Bay and Narrows.

In order to show the difference in the amount of pollution which might exist in the water at different depths in the Lower Bay, a series of samples was collected near Coney Island and the Narrows. The results are given in table 10.

Table 10. Results of chemical analyses of water taken at various points at different depths in the Lower Bay and Narrows. The samples were collected from a boat on February 17, 1906, between 2:45 and 4:40 p. m. High water occurred at Sandy Hook at 2:39 p. m., and at Governor's Island at 2:55 p. m. The wind was southwest to south and averaged 6½ miles per hour. (Results stated in parts per million.)

88	Off Norton's Point, Lower Bay....	3:00	40	.280	.180	15,300
89	Off Norton's Point, Lower Bay....	2:45	80	.250	.280	15,500
90	Narrows	4:40	5	.260	.200	12,800
91	Narrows	4:25	40	.130	.130	14,400
92	Narrows	4:10	80	.275	.275	14,800

Table 10 shows that the extent of the pollution did not, in this case, vary inversely as to depth. There were larger amounts of free and albuminoid ammonia near the surface and at the bottom than in the middle. These differences were marked. It appeared that a stratum of water containing more sewage than was found in the Upper Bay lay at the top and bottom, while the water between was in a somewhat less contaminated condition.

The chlorine results show that the water was considerably salter at the bottom than at the top.

These chemical conditions formed an exception to the rule which had been observed thus far, that is, that there was more sewage at the surface than below.

3. Chemical Condition of Water of New York Bay and Lower Ends of East and North Rivers.

Samples of water were taken at different points in the vicinity of the Upper Bay and analyzed chemically with the results given in table 11.

Table 11. Results of chemical analyses of water taken from various points in the Upper Bay and lower ends of the East and North rivers. The samples were collected from a boat on March 2, 1906, between 11:00 a. m. and 5:15 p. m. At Governors Island high water occurred at 12:20 p. m., and low water at 7:10 p. m. The wind was east and northeast and ranged from 5 to 9 miles per hour. (Results stated in parts per million.)

3155

On the occasion when the samples were collected for table 11, there was a larger amount of sewage in the water than had been observed previously. Some of the samples, although not collected near obvious sources of pollution, contained relatively large amounts of free ammonia. The water in the lower end of the East River was notable in this respect.

4. Chemical Condition of the Waters of the Rivers Surrounding Manhattan Island.

Samples of water taken from the East River, Harlem River and Hudson River were analyzed chemically with the results given in table 12.

Table 12. Results of chemical analyses of water taken from various points in the waters surrounding Manhattan Island. The samples were collected from a boat at a depth of one foot below the surface, unless otherwise indicated, on April 1, 1906, between 9:55 a. m. and 3:05 p. m. High water occurred at Governors Island at 12:30 p. m. The tide was low at Governor's Island at 7:16 a. m. and at Willetts Point at 10:13 a. m. The wind was northwest and ranged from 17 to 32 miles per hour. (Results stated in parts per million.)

The water of the East River contained, on an average, more free and albuminoid ammonia than the waters of the Hudson or Harlem rivers. It was, therefore, decidedly more polluted.

There was little difference between the water at the surface and at the bottom, so far as the ammonias indicated.

There was much more sea water in the East River than in the Hudson or Harlem rivers.

The condition of the Harlem River, as indicated by these analyses, was not far different from that of the Hudson.

The results of the determinations of chlorine show that the Hudson River was comparatively fresh as far south as the middle of Manhattan Island, except at the bottom. There was much more salt water near the bottom than at the top. A sample collected near the bottom, off Grant's Tomb, contained about thirteen times as much chlorine as the average of the surface samples above 40th street.

Off the Battery there was nearly twice as much sea water at the bottom as at the top.

There was a steady decrease in the amount of salt water in the Harlem River from the East River to the Hudson.

4. Amount of Oxygen Found in the Waters of New York Bay and Vicinity.

Inasmuch as the digestion of sewage in the tidal waters about New York depends largely upon their supply of oxygen, a series of analyses was made to determine whether these waters contained as much oxygen as they should have. Tables 13, 14 and 15 give the results of the oxygen determinations at different depths in the waters of the Upper and Lower bays.

Table 13. Results of analyses of water for oxygen taken from various points at different depths in Upper New York Bay. The samples were collected from a boat on January 28, 1906, between 10:00 a. m. and 3:30 p. m. At Governors Island the tide was high at 10:40 a. m., and low at 5:12 p. m. The wind was north to northwest with a minimum velocity of 4 miles per hour, between noon and 1:00 p. m., and 13 miles per hour between 3:00 and 4:00 p. m. (Results stated in cubic centimeters of oxygen per litre of water.)

30 The three foregoing tables show that there was always enough oxygen in the water to insure a sufficient supply for the bacteria of decomposition. Under such circumstance no offensive odors would be formed by them.

In many cases the amount of oxygen increased with the depth. Samples taken near the surface usually did not have as much oxygen as samples from below. This was contrary to what might have been expected and seems to show that the disproportionately large numbers of bacteria of decomposition which exist near the surface consume enough of the oxygen to visibly reduce its amount.

Oxygen determinations were also made of samples of water collected at the surface at a number of other points in the vicinity of New York. The results are given in tables 16 and 17.

Table 16. Results of analyses of water for oxygen taken from various points in the Upper Bay and lower ends of the East and North rivers. The samples were collected from a boat on March 2, 1906, between 11:25 a. m. and 5:05 p. m. At Governors Island high water occurred at 12:20 p. m., and low water at 7:10 p. m. The wind was east and northeast and ranged from 5 to 9 miles per hour. (Results stated in cubic centimeters of oxygen per litre of water.)

northwest and ranged from 17 to 32 miles per hour. (Results stated in cubic centimeters of oxygen per litre of water.)

It will be observed that the oxygen was exhausted in only one of the samples examined, that is, in that one which was collected from the Gowanus Canal. There was a decided reduction below the average in the amount of oxygen in the water of the bay opposite the outlet of the Gowanus Canal and also near the outfall of the large trunk sewer at 65th street, Brooklyn. This showed the effect of sewage contamination.

In samples collected in the Hudson River and East River there was no deficiency of oxygen.

The difference between the oxygen at the bottom and near the surface of the water was noticeable in the Hudson off Grant's Tomb. Here there was more oxygen at the surface than at the bottom.

32 C—Results of a Sanitary Inspection of the Shores of New York Bay.

An inspection of the shores of New York Bay was undertaken in the latter part of March and continued until the middle of April, 1906. The object of this inspection was to observe such sewage or other pollution as might exist on or near the shores. A sanitary inspector, Dr. Payne B. Parsons, walked along the shore line and made note of sewage and refuse on the shores and in the water within his range of view.

The conditions found are given in the following tables.

Table 18. Results of a sanitary inspection of the Staten Island shore of New York bay.

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1906. Mar. 27	a. m. 10:15	Midland Beach	S. W.	Ebb	Driftwood (large amount), tin cans, bottles, crockery, bones, shoes, rags, paper, shells, vegetables, dead animals, straw and fibrous material, seaweed, etc. Offensive odor.
Mar. 27	11:30	South Beach, about 100 yards of lower part.	S. W.	Ebb	In 400 square feet of shore about 1-20 cubic yard of vegetable matter, 1-20 cubic yard of animal matter and 1-2 cubic yard wood.
Mar. 27	p. m. 2:00	South Beach to Fort Wadsworth.	S.	Ebb	In 400 sq. ft. of shore about 1-30 cu. yd. of vegetable matter, 1-30 cu. yd. of animal matter and 1-2 cu. yd. of driftwood.
Mar. 28	a. m. 9:30	From upper (northern) limit of Fort Wadsworth north 100 yds.	N. W.	Flood.	Large amount of driftwood. Much less general refuse than at South Beach. Very little garbage. Two dead animals.
Mar. 28	10:00	Last point to foot of Cliff street, Rosebank.	N. W.	Flood.	Much driftwood, bottles, rags, cans, etc. Not much garbage.
Mar. 28	10:40	Foot of Cliff street to foot Pennsylvania ave., Rosebank.	N. W.	Ebb	Same as preceding.
Mar. 28	11:20	South of Doyle's wharf, about 200 yds. north of Pennsylvania ave.	N.	Ebb	Not much driftwood or garbage. Considerable amount of grease floating in water. Water polluted with a considerable amount of sewage. Nearest sewer foot West street, 100 yds. away. Did not appear from tide and wind to come from this.
Mar. 28	p. m. 12:05	Foot West st., Clifton	N. W.	Ebb	Much driftwood. Not much garbage. Surface of water covered with petroleum. Large sewer outlet here did not appear to change appearance of water. Odor very offensive from number of small sewers opening at side of street, 100 ft. from the shore. In 400 sq. ft. about 1-2 cu. yd. vegetable and 1-10 cu. yd. animal. No driftwood.
Mar. 29	a. m. 9:15	Foot of Dock st., Stapleton.	N.	Flood.	Grease and petroleum floating near shore. Driftwood, garbage, mattresses, house sweepings and formed fecal matter, the latter breaking up as it was observed, indicating that the sewage mostly came from sewer emptying at foot of street.
Mar. 29	10:00	Foot of Thompson st.	N.	Flood.	Same as preceding. Sewer emptied here. Sewage probably from this sewer.
Mar. 29	10:20	Foot of Canal st.	N. W.	Flood.	Several small sewers located here. Same conditions as above.
Mar. 29	10:40	Foot of Water st.	N. W.	Ebb	Two large sewers near together. Water covered with grease and sewage. Shore covered with sewage and general refuse. Formed feces in water and on shore. Great quantity of street sweepings and refuse from grain mill nearby. Odor offensive. Worst place found so far. No driftwood. In 400 sq. ft. of shore 1 cu. yd. vegetable matter and 1-10 cu. yd. animal matter.

Table 18.—*(Concluded.)*

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1906	a. m.				
Mar. 29	11:30	Foot of Prospect st.....	N.....	Ebb...	Pier being made by dumping; some refuse falling over sides. Large sewer here, also. In 400 sq. ft. of shore about 1-5 cu. yd. vegetable, and 1-10 cu. yd. animal matter. Hardly any driftwood.
Mar. 29	m. 12:00	Foot of Wave st.....	N.....	Ebb...	Shore much cleaner. Some petroleum and grease on water.
Mar. 29	p. m. 12:15	Williams' lumber yard..	N. W..	Ebb...	Scum of grease, straw and wood about docks; large sewer. Water contains sewage, including formed feces. On shore, in 400 sq. ft., about 1-5 cu. yd. vegetable and 1-10 cu. yd. animal matter.
Mar. 29	1:30	Foot of Marietta st., Tompkinsville.	N. W..	Ebb...	Very large sewer. Water contains sewage near shore. In 400 sq. ft., about 1-5 cu. yd. vegetable and 1-10 cu. yd. animal matter; all this from sewer, apparently.
Mar. 29	2:15	Docks of Amer. Dock Stores, Tompkinsville	N. W..	Ebb...	Along docks saw some sewage, trace of garbage, fibrous matter and wood.
Mar. 29	3:00	Foot of South st., St. George.....	N. W..	Ebb...	Kerosene on water, also wood, fibre and some garbage.
Mar. 30	a. m. 9:20	Ferry Docks, St. George.	E.....	Flood.	Scum of grease and kerosene, fibrous material, garbage, wood, etc., floating about the docks. No odor. No sewage noticed.
Mar. 31	9:20	B. & O. Docks, St. George.	N. W..	Flood.	Petroleum, wood, straw and some garbage along docks.
Mar. 31	9:50	Foot Church st., New Brighton.	N. W..	Flood.	Petroleum and some driftwood.
Mar. 31	10:20	Foot Westervelt ave., New Brighton.	N.....	Flood.	Sewer here. Sewage from this, also petroleum. Some garbage and wood in water. Estimated 1-30 cu. yd. vegetable and 1-60 cu. yd. animal matter in 400 sq. ft. Two sewers here. Sewage on shore and in water from this sewer.
Mar. 31	11:30	Foot Tyson st., New Brighton.	N.....	Ebb...	Sewer here. Shore same as Lafayette st.
Mar. 31	11:50	Snug Harbor Dock....	N.....	Ebb...	Petroleum from Bayonne shore along dock. Some garbage and wood.
Mar. 31	p. m. 12:10	Between Snug Harbor and Livingston.	N. W..	Ebb...	Large open sewer empties into inlet. Shore of inlet lined with sewage, garbage, rags, paper and wood. 1-30 cu. yd. vegetable and 1-60 cu. yd. animal matter in 400 sq. ft.
Mar. 31	12:30	Club house Dock, Richmond Terrace.	N. W..	Ebb...	Petroleum and wood. No sewage.
Mar. 31	1:50	Foot Tompkins place, West New Brighton. Inlet from Tompkins place to Duncan st.	N. W..	Ebb...	Sewers open into inlet made by new railroad filling. Shore and water of inlet filthy. Odor offensive. ½ cu. yd. vegetable and 1-20 cu. yd. animal matter in 400 sq. ft.
Mar. 31	2:35	Bodine Creek, Port Richmond, near corner Richmond Terrace and Jewett ave.	N. W..	Ebb...	Shores of brook full of sewage. Many sewers empty into it. Garbage on shore. Odor offensive. Water full of sewage. Scum of grease and petroleum. Drinking ground for oysters. 1-30 cu. yd. vegetable and 1-60 cu. yd. animal matter on shore in 400 cu. ft.
Mar. 31	3:40	Port Richmond ave., Port Richmond, Bergen Beach ferry docks.	N. W..	Ebb...	Petroleum. Some garbage, wood, straw, etc. No sewage noticed.

This table shows that the Staten Island shore accumulates considerable quantities of refuse which is carried to it by the tide. Some portions of the shore are decidedly foul with sewage which is discharged by sewers from Staten Island itself.

Table 19. Results of a sanitary inspection of the New Jersey shore of New York bay.

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1906.	a. m.				
Apr. 2	9:50	Bergen Point, Bayonne.	N. W..	Flood.	Some wood. No garbage or sewage.
Apr. 2	10:20	Foot of Hobart ave., Bayonne.	N. W..	Flood.	Rocky shore. No garbage or sewage.
Apr 2.	11:10	East end of Standard oil tanks, Bayonne	N. W..	Flood.	Petroleum on water and shore, wood. Two dead animals. About 1-30 cu. yd. vegetable and 1-40 cu. yd. animal matter in 400 sq. ft. of shore.
Apr. 2	11:35	Bayonne Yacht Club....	N. W..	Flood.	Rocky shore. No sewage or garbage. Petroleum on water.
Apr. 2	p. m. 1:05	Shore near Bayonne station, Lehigh Valley Railroad.	N. W..	Flood.	Two sewers here, 4 ft. in diameter each. Water discolored with sewage within radius of 100 yds. Also petroleum on water. Some wood and garbage, pipes, rags, etc. on shore. About 1-40 cu. yd. vegetable and 1-80 cu. yd. animal in 400 sq. ft. of shore.
Apr. 2	2:10	Foot 46th st., Bayonne.	N. W..	Ebb...	Shore free from garbage. No sewage noticed. Some wood and petroleum on water.
Apr. 3	a. m. 9:40	Foot East 49th st., Bayonne.	N. W..	Flood.	Large brick sewer here ending at high water mark. Sewage flows over beach, tide being low. Some refuse on shore. In 400 sq. ft. of shore, 1-30 cu. yd. vegetable and 1-60 cu. yd. animal matter. Odor 500 ft. leeward.
Apr. 3	10:20	Midway between 49th st. and Penn. Railroad wharf.	N. W..	Flood.	No trace of sewage. Some refuse In 400 sq. ft. of shore, about 1-30 cu. yd. vegetable and 1-60 cu. yd. animal matter.
Apr. 3	11:10	Penn. Railroad freight ferry house at end of point.	N. W..	Flood.	Scum of sewage on water from large sewer nearby. Some garbage and wood in water about dock.
Apr. 3	11:30	Penn. Railroad wharf...	N. W..	Flood.	A 5 ft. iron sewer runs out nearly to end of point on north side parallel to shore. Sewage from this sewer on shore and in water toward end of wharf. Odor not offensive on wharf.
Apr. 3	12:10	Shore opposite Bay View Cemetery, Greenview.	N. W..	Flood.	Large sewer (4 ft. iron) empties here. Runs over flats (swampy); could not reach end of it at shore.
Apr. 3	a. m. 12:20	Cavan's Point.....	N. W..	Flood.	No odor at railroad tracks. Cavan's Point shore free from garbage and sewage as far as could be seen.
Apr. 3	1:40	End of National docks, Point nearest Liberty Island.	N. W..	Flood.	Some driftwood along dock. No garbage; no sewage.

Table 19.—(*Concluded.*)

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1906. Apr. 3	p. m. 2.15	Shore of Point opposite Ellis Island.	N. W.	Flood.	Some garbage, driftwood and petroleum on surface of water. In 400 sq. ft. of shore 1-30 cu. yd. vegetable and 1-60 cu. yd. animal matter.
Apr. 3	3.20	Shore between National docks and Communipaw.	W.	Ebb.	Garbage, paper and wood along docks. No sewage found.
Apr. 4	a. m. 9.25	Foot of Communipaw ave.	S. W.	Ebb.	Small sewer. Scum of grease on water. Sewage on shore. Odor had 200 ft. to leeward. No garbage.
Apr. 4	9.50	200 yds. north of Communipaw ave., along shore.	S. W.	Ebb.	A 2 ft. iron pipe empties between flats 100 ft. from shore. Runs from dredger 1 mile away, 150 yds. west of Ellis Island. Pipe discharges from free end and from cracks, sewage with coal from bottom of bay. Sewage has offensive odor. Whitish, greasy.
Apr. 4	11.05	Shore opposite Ellis Island, Jersey City.	S. W.	Flood.	Scum of grease on surface of water. Sewage on shore apparently stirred up by dredging near nearby.
Apr. 4	p. m. 12.10	Shore beside North River Coal Co. wharf, Jersey City.	S. W.	Flood.	Scum of grease on water. Odor of sewage 50 ft. to leeward. No garbage. Hardly any sewage on shore.
Apr. 4	1.45	Freight docks Central Railroad of New Jersey, Jersey City.	S. W.	Flood.	Scum of sewage on surface of water. Some garbage, wood and paper floating about dock. Some petroleum. No odor noticeable.

The New Jersey shore of the Upper New York Bay was, on the whole, comparatively free from visible traces of sewage except in the neighborhood of the outfalls of local sewers.

Table 20. Results of a sanitary inspection of the Brooklyn shore of New York Bay.

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1906. Apr. 5	a. m. 9.10	Fulton Ferry dock.....	N. W.	Ebb...	Scum on surface of water in slip due to sewage. Some wood, garbage, paper and flies.
Apr. 5	9.25	N. Y. Dock Co., Rear of warehouse No. 35.	N. W.	Ebb...	Scum of grease on water; garbage, wood flies. No odor noticeable.
Apr. 5	9.50	N. Y. Dock Co., Rear of warehouse No. 30.	N. W.	Ebb...	Petroleum on surface. Odor plain.
Apr. 5	10.15	N. Y. Dock Co., West side Red D line pier.	N. W.	Ebb...	Large quantity of sewage in water. Water discolored. Scum of grease on surface. Odor 50 ft. to leeward. Paper, rags, wood, straw and garbage. Human feces noted in water.
Apr. 5	10.35	Wall st. ferry, Brooklyn.	N. W.	Ebb...	Some straw and garbage in slips.
Apr. 5	10.55	N. Y. Dock Co., between piers Nos. 13 and 14.	N. W.	Ebb...	Petroleum on surface. Odor plain.
Apr. 5	11.10	Between piers Nos. 16 and 17	N. W.	Ebb...	Large quantity of wood and flies, also garbage, bottles and paper.

Table 20.—(*Continued.*)

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1905.	a. m.				
Apr. 5	11:20	Between piers Nos. 17 and 18.	S.W..	Flood.	Same as between piers Nos. 16 and 17.
Apr. 5	11:35	West side of pier No. 19.	S.W..	Flood.	Scum of sewage on surface. Odor not bad. Wood straw, paper and garbage.
Apr. 5	11:50	Atlantic ave. ferry, Brooklyn.	S.W..	Flood.	Scum of sewage on surface. Wood, straw, papers. Odor carried 40 ft. leeward.
Apr. 5	p. m. 12:15	East side grain elevator, N. Y. Dock Co.	S.W..	Flood.	Scum of sewage on surface. Large quantity of grain refuse in water. Wood and flour, some petroleum.
Apr. 5	1:10	Foot of Amity st.....	S.W..	Flood.	Large quantity of wood. Sewage on surface. Odor 50 ft. leeward; garbage, bottles, grain. In 400 sq. ft. of shore; vegetable matter 2 cu. yds., including wood, animal matter 1-40 cu. yd.
Apr. 5	1:25	Between piers Nos. 35 and 36. Foot Congress st.	S.W..	Flood.	Scum of sewage along dock. Some petroleum.
Apr. 5	1:50	Foot of Baltic st., opposite Governor's Island.	S.W..	Flood.	Sewage in water; water discolored. Scum of grease on surface. Odor 75 ft. leeward. Some wood.
Apr. 5	2:10	Foot Sedgwick st. or street end of slip.	W.....	Flood.	Scum of sewage on surface. Some wood and garbage.
Apr. 5	3:05	At end of pier opposite center of Governor's Island.	W.....	Flood.	No sewage or garbage seen on surface.
Apr. 5	3:35	Foot of DeGraw st.....	W.....	Flood.	Large amount of sewage in water. Water discolored with it. Odor 30 ft. to leeward. Scum of grease on surface.
Apr. 5	3:50	Foot of Hamilton ave., just west of ferry house.	W.....	Flood.	Scum of sewage on surface. Odor of sewage noticeable. Sewer empties here. Wood and paper, dead fish, tin cans and garbage.
Apr. 5	4:20	Hamilton ave. ferry slips.	S.W..	Flood.	Scum of sewage on water. Garbage, wood and paper in water.
Apr. 6	a. m. 9:10	Atlantic basin. Wharf foot Summit st.	N.W..	Ebb...	Large quantity of wood, also garbage, paper and bottles. Scum of sewage on surface.
Apr. 6	9:25	Between piers Nos. 34 and 35 and between pier No. 35 and warehouse.	N.W..	Ebb...	Same as above. Odor of sewage noticeable 40 ft. to leeward.
Apr. 6	9:35	Atlantic basin wharf in rear of bonded warehouses. N. Y. Dock Co.	N.W..	Ebb...	Good deal of driftwood. Some garbage. Scum of sewage on surface in spots. Odor not apparent, except nearby.
Apr. 6	10:00	West side of Atlantic basin.	N.W..	Ebb...	Some wood and garbage. Very little evidence of sewage.
Apr. 6	10:20	Foot of Jewett st.	N.W..	Ebb...	Some wood and garbage in water about docks. No sewage found.
Apr. 6	10:45	Foot of Ithaman st.....	N.W..	Ebb...	Some wood and garbage. Water discolored with sewage to slight extent. Scum of grease on surface.
Apr. 6	11:30	West of pier No. 29....	N.W..	Ebb...	Large quantity of driftwood, also rags, paper and garbage. No sewage seen.
Apr. 6	11:50	Foot of Conover st.....	N.W..	Ebb...	Water discolored with sewage. Scum of grease on surface. No sewer here. Dead dog, wood and garbage on shore. In 400 sq. ft. of shore 1-30 sq. yd. vegetable and 1-30 sq. yd. animal matter.
Apr. 6	p. m. 1:10	Erie Basin, north end, nearest Beard st.	N.W..	Flood.	Scum of sewage on surface. Odor not noticeable. Driftwood.
Apr. 6	1:25	Foot of Richards st., Erie basin.	N.W..	Flood.	Scum of sewage on water. Some wood, garbage, cotton and fibrous material in water.

Table 20.—*Continued.*

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1906.	p. m.				
Apr. 6	2:05	Erie basin, between Richards and Dwight sts.	N. W.	Flood	Large quantity of machine oil on surface of water from machine shops nearby. Sawdust and many small dead fish floating on surface of water.
Apr. 6	2:15	South end of Erie basin	N. W.	Flood	Good deal of driftwood on surface of water. No sewage.
Apr. 9	a. m. 9:25	Wharf between Erie basin and Gowanus bay.	N.	Ebb	Scum of sewage on surface of water on both sides of wharf. Some garbage and wood. No odor.
Apr. 9	9:30	Brooklyn basin, near entrance to Gowanus bay.	N.	Ebb	Scum of sewage on surface; wood and garbage. No odor.
Apr. 9	10:20	Inner shore of Brooklyn basin.	N.	Ebb	Scum of sewage on surface; wood and garbage. No odor.
Apr. 10	9:18	Off Gowanus bay on course of 39th st. ferry.	S. W.	Ebb	Scum of sewage on water. Some driftwood and garbage.
Apr. 10	9:25	Ferry slip, foot 39th st., Brooklyn.	W.	Ebb	Scum of sewage on water. No odor.
Apr. 10	9:30	Foot of 42nd street	W.	Ebb	Scum of sewage on water. Straw, paper, rags, garbage and feces. Water discolored with sewage. No odor.
Apr. 10	10:05	Foot 43d st.	W.	Ebb	Same as at 42nd st.
Apr. 10	10:20	Between piers Nos. 4 and 5. Bush docks. Between pier 2 and 4.	S. W.	Ebb	Scum of sewage. Salmon cans and wrappers in water.
Apr. 10	10:30	West of Bush docks. Shore foot 51st st.	S. W.	Ebb	Large quantity of sewage—scum on surface. Water discolored. Odor 50 ft. to leeward. In 600 sq. ft. of shore ½ cu. yd. vegetable matter.
Apr. 10	11:10	Shore between 53rd and 54th st., Brooklyn.	S.	Ebb	Scum of sewage on water; garbage and wood. In 600 sq. ft. of shore ½ cu. yd. vegetable matter.
Apr. 10	11:25	Morse Dry Dock Co., foot 56th st.	S.	Ebb	Scum of sewage on surface, about docks. Driftwood. No odor.
Apr. 10	11:35 a. m.	Foot 57th st.	S.	Ebb	Same as at 56th st.
Apr. 10	12:15	Shore just west of 57th st.	S. E.	Ebb	Scum of sewage. Odor 50 ft. to leeward. In 600 sq. ft. of shore ½ cu. yd. vegetable matter.
Apr. 10	1:10	Foot of 65th st.	S. E.	Ebb	Large sewer running out to pierhead line, under wharf. The sewage sets back toward south, toward Edison Co.'s plant. Water discolored for several hundred yards with sewage. Scum on surface. Odor not bad. Small grease balls on surface of water, the size of marbles.
Apr. 10	1:50	Along shore road of Bay Ridge.	S. E.	Ebb	Small sewers. Scum of sewage on water. No odor.
Apr. 10	2:20	Dock foot 69th st.	S. E.	Flood	Scum of sewage both sides of dock. No odor.
Apr. 10	2:30	South shore of dock.	S. E.	Flood	Water discolored with sewage—scum on surface. Small grease balls. Odor 50 ft. to leeward. Several sewers here run out to beyond low water mark.
Apr. 10	2:50	Foot 71st., Bay Ridge.	S. E.	Flood	Large brick sewer. Water discolored with sewage in 100 yds. radius. Scum grease on surface. Sewage sets toward Narrows (south).
Apr. 10	3:30	71st to 79th st., along shore.	S. E.	Flood	Scum of sewage on surface. Several small sewers. Some driftwood.
Apr. 10	4:10	Foot 79th st.	S. E.	Flood	Sewer, similar to 65th st. sewer, covered, out to pierhead line. Sewage sets toward Narrows (south). Water discolored for several hundred yards. Odor not bad.

Table 20.—*Concluded.*

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1905.	a. m.				
Apr. 11	9:35	Shore between 79th st., Bay Ridge and Crescent Athletic Club.	N. E.	Ebb...	Scum of sewage on surface. Some driftwood. No odor.
Apr. 11	9:50	Back of Crescent Club House.	N. E.	Ebb...	Two sewers. Scum of grease on surface. Driftwood, bottles, tin cans. Sewer at high water mark. Odor 20 ft. to leeward. In 400 sq. ft. of shore 1 cu. yd. vegetable matter.
Apr. 11	10:15	100 yards south Crescent Club.	N. E.	Ebb...	Small sewer out to pierhead line. Scum of grease on surface. Some wood and garbage.
Apr. 11	10:25	Shore on to 88th st.....	N. E.	Ebb...	Less sewage. Considerable wood.
Apr. 11	10:30	Side of private dock south of 88 th st.	N. E.	Ebb...	More sewage. Wood and paper in water.
Apr. 11	11:15	Foot 92nd st.....	N. E.	Ebb...	Big sewer covered out to pierhead line. Scum of sewage both sides pier. Water slightly discolored. Odor not strong. Grand deal of wood nearby.
Apr. 11	11:25	Shore between 92nd st. and low flats south.	N. E.	Ebb...	Fairly free from sewage. Some wood.
Apr. 11	11:25	Off flats (old dock)	N. E.	Ebb...	Hardly any sewage. Two small sewers.
Apr. 11	11:45	Just south of flats.....	N. E.	Ebb...	Water discolored and scum of sewage on surface.
Apr. 11	11:50	Foot 3rd ave.....	N. E.	Ebb...	Seaweed piled up in corner of shore 3 ft. high.
Apr. 11	p. m. 12:00	Foot 4th ave., north of dock.	N. E.	Ebb...	Good deal of sewage. Grease ball 2 in. x 2 in. Garbage and wood. No odor. In 400 sq. ft. of shore 4 cu. yd. vegetable and 1-10 cu. yd. animal matter.
Apr. 11	12:25	Between 4th ave. and Fort Hamilton.	N. W.	Ebb...	Shore free from sewage.

The eastern, or Brooklyn, shore of Upper New York Bay was, for nearly its whole length, obviously polluted with sewage, refuse and garbage. The amount of this pollution diminished in the direction of the Narrows.

Table 21. Results of a sanitary inspection of the shore of the islands in the Upper Bay.

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1905.	a. m.				
Apr. 7	9:10	Governor's Island, immediately west of ferry dock.	N. W.	Ebb...	Sewage in water. Formed feces. No odor. Some wood and fiber. Mattress.
Apr. 7	9:25	Governor's Island, 150 yds. west on north shore.	N. W.	Ebb...	Two sewers. Scum of sewage on surface. Sewage in water. Feces and tissue paper. Horse droppings. Little driftwood. No odor.
Apr. 11	9:45	Governor's Island, 200 yds. west of ferry dock.	N. W.	Ebb...	Sewer. Odor 50 ft. to leeward. Some scum of sewage on surface.

Table 21.—(*Concluded.*)

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1906.	a. m.				
Apr. 7	10:10	Governor's Island, near wharf on north shore.	N. W..	Ebb...	Water discolored with sewage. Scum of grease on surface. Toilet paper, feces. Odor 50 ft. to leeward. Sewer near. Sewage from this sewer.
Apr. 7	10:25	Governor's Island, west side Castle Williams.	N. W..	Ebb...	Water discolored with sewage. Scum of grease on surface. Toilet paper and feces. Odor 20 ft. to leeward. No garbage or wood.
Apr. 7	10:50	Governor's Island, along bulkhead on west shore to retain filling.	N. W..	Ebb...	Large quantity of floating wood, garbage and straw. Scum of sewage on surface, also feces. Some odor. Sewage seemed to come from distance. No sewers near. Current from Brooklyn shore.
Apr. 7	11:10	Governor's Island inlet where filling is being done	W	Ebb...	Scum of grease on surface of water.
Ap. 7.	11:25	Governor's Island inlet, near dredges.	W....	Ebb...	No sewage noticed in mud pumped from Buttermilk channel. No odor.
Apr. 7	11:50	Governor's Island, along bulkhead on south shore.	W....	Ebb...	Some sewage near small sewer at beginning of wall. Very little wood and garbage.
	p. m.				
Apr. 7	12:20	Governor's Island, east shore.	W....	Ebb...	Water discolored with sewage for 200 yds. from nearby sewers. Toilet paper and feces.
Apr. 7	12:30	Governor's Island, cable crossing.	W....	Ebb...	Sewage from sewer here.
Apr. 7	1:20	Ellis Island, ferry slip...	W....	Flood.	Scum of sewage on surface. Some garbage and paper in water. Water discolored with sewage at one point.
Apr. 7	1:35	Ellis Island. New Hospital wharf, south side	W....	Flood.	Some wood and garbage. New wharf being made by dumping between here and Liberty Island. Men seemed to be careful in trimming.
Apr. 7	1:45	Ellis Island, southwest extremity.	W....	Flood.	Slight scum of sewage on surface.
Apr. 7	2:00	Ellis Island, west shore opposite Black Tom.	W....	Flood.	Sewer near. Water discolored with sewage. Scum of grease on surface. Shore and water covered with paper, rags, wood, tin cans, garbage. Great quantity of garbage. In 400 sq. ft. shore 1-10 cu. yd. vegetable and 1-40 cu. yd. animal matter.
Apr. 7	2:10	Ellis Island, off coal dock	W....	Flood.	Scum of sewage on surface.
Apr. 7	2:15	Ellis Island, north shore opposite Lehigh Valley freight station, Communipaw.	W....	Flood.	Scum of sewage from nearby sewers. No odor. Feces in water.
Apr. 7	2:25	Ellis Island, east shore, opposite Manhattan.	W....	Flood.	No garbage or sewage along docks.
Apr. 7	3:20	Liberty Island, north side toward Ellis Island.	W....	Flood.	Water muddy from wind. Could not detect sewage. Bones on shore. Two or three small sewers. No odor.
Apr. 7	3:35	Liberty Island, west shore, opposite National docks.	W....	Flood.	Scum of sewage on surface, straw and driftwood. No sewers on this shore. Water not discolored with sewage. No odor.
Apr. 7	3:50	Liberty Island, south shore Liberty Island, opposite Staten Island.	W....	Flood.	Considerable sewage in water. Scum of grease on surface all along shore. Only one small sewer on this shore. The sewage comes from a distance. No odor. Water somewhat discolored with sewage. Some straw on water.
Apr. 7	4:20	Liberty Island, east shore Liberty Island, near boat landing.	W....	Flood.	Slight scum of sewage on surface. Considerable wood. Some garbage in the water.

The shores of the islands of the Upper Bay were, for the most part, comparatively clean, except for sewage which was evidently discharged from buildings on the islands themselves. There were points, however, on Governor's Island and Liberty Island where remains of sewage were found which could not have originated nearby. This was long range pollution of the most objectionable character.

Table 22. Results of a sanitary inspection of the shores of New York Bay from the Narrows to Coney Island and Sheepshead bay.

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1906.	p. m.

Apr. 12	3:10	Same shore near Coney Island creek outlet...	N. W..	Ebb...	Slight scum on surface from waters of creek. No odor.
Apr. 12	3:50	Same shore, along flats near Coney Island.	N. W..	Ebb...	No sewage. Some seaweed.
Apr. 12	4:20	Bridge over Coney Island creek.	N. W..	Ebb...	Several sewers empty into creek between bridge and Gravesend bay. Scum of sewage on surface of creek. No odor.
	a. m.				
Apr. 13	10:05	South shore of Gravesend bay from Coney Island creek to Sea Gate.	N. W..	Flood.	Scum of sewage on surface; feces, house sweepings and toilet paper on water. About 12 sewers along this shore, one at foot of each street. Odor not bad.
Apr. 13	10:55	Southwest shore of Gravesend bay.	N. W..	Flood.	Good deal of driftwood on shore. Scum of sewage on water. In 400 sq. ft. of shore ½ cu. yd. vegetable matter.
Apr 13	11:25	Shore of Gravesend bay, around east side of Norton's Point.	S....	Ebb...	Great quantity of driftwood and some garbage on shore. Scum of sewage on surface of water. Grease balls 3 in. x 3 in. No sewers nearby. Driftwood and sewage backs in from New York bay with the tide. (Men gathering wood on shore, said new supply came in every day.) In 400 sq. ft. of shore 3 cu. yds. vegetable matter, mostly wood, 1-20 cu. yd. animal matter.
Apr. 13	11:50	Shore off Norton's Point to Atlantic Yacht Club House at end of Gravesend bay.	S.....	Ebb...	Scum of sewage on surface. Two grease balls, 2 x 2 and 3 x 3 inches. No odor of sewage. Some garbage and driftwood on water.
	p. m.				
Apr. 13	12:25	Shore of New York bay, Sea Gate west of Norton's Point.	S.....	Ebb...	Immense quantity of driftwood. In 400 sq. ft. of shore, 5 cu. yds. Some garbage, straw and bottles. No sewage on water. Grease ball on shore 2 x 2 in.
Apr. 13	1:20	Shore off Sea Gate to Coney Island light.	S. E...	Ebb...	Great quantity of driftwood. Some garbage. No sewage detected.
Apr. 13	2:15	South shore Sea Gate from light to Seabourne hotel.	S. E...	Ebb...	Some driftwood where shore runs back some distance. Some seaweed. Very little garbage. No evidence of sewage.
Apr. 13	3:10	Seabourne Hotel to Sea Gate Beach Hotel	S. E...	Ebb...	Not much driftwood. Some straw on shore and seaweed No sewage.
Apr. 13	3:55	Sea Gate Beach hotel to Steeplechase Park, Coney Island.	S. E...	Ebb...	Not much driftwood or garbage. Considerable amount of straw and seaweed. No sewage.
Apr. 13	4:20	Off Steeplechase Park...	S. E...	Ebb...	Shore very clean all along here.
Apr. 14	9:30	Coney Island shore from Steeplechase Park to Dreamland.	S. E...	Flood.	Shore quite clean Some seaweed and driftwood. No remains of sewage visible.
Apr. 14	9:55	Shore of Dreamland....	S. E...	Flood.	Some seaweed.
Apr. 14	10:25	Beach from Dreamland to iron pier.	S. E...	Flood.	Small quantity of seaweed. No garbage or sewage.
Apr. 14	10:50	Palmer's bathing beach.	S. E...	Flood.	Beach clean.
Apr. 14	11:15	Municipal shore east of Palmer's.	S. E...	Flood.	Some seaweed.
Apr. 14	11:45	Parkway baths, south..	S. E...	Flood.	Large quantity of seaweed on shore. In 400 sq. ft. of shore 2 cu. yds. of seaweed.
	p. m.				
Apr. 14	12:20	Between Parkway baths and Brighton Beach hotel.	S. E...	Ebb...	Large quantity seaweed, 4 cu. yds. in 400 sq. ft. of shore. Dead dog.

Table 22.—(*Concluded.*)

Date.	Time.	Place.	Wind.	Tide.	Condition of shore.
1906.	*p. m.*				
Apr. 14	1:15	Shore just east of Brighton Beach hotel.	S. E...	Ebb...	Immense quantity seaweed. Six cu. yds. in 400 sq. ft. of shore. Some driftwood. Small quantity garbage.
Apr. 14	1:50	Shore front of Manhattan Beach hotel.	S. E...	Ebb...	Some seaweed along seawall.
Apr. 14	2:20	From Manhattan Beach hotel to Oriental.	S. E...	Ebb...	Seaweed on water along seawall.
Apr. 14	2:45	Front of Oriental hotel..	S. E...	Ebb...	Seaweed along seawall.
	a. m.				
Apr. 16	9:20	Sheepshead bay foot of shore road.	N.....	Flood.	Scum of sewage on surface near shore. Small amount of garbage and seaweed. No odor.
Apr. 16	9:50	Shore road to Ocean ave.	N.....	Flood.	No sewage noticed.
Apr. 16	10:25	Ocean ave. to foot East 23rd st.	N. W..	Flood.	Some seaweed. No sewage.
Apr. 16	10:45	East 23rd st. to East 27th st.	N. W..	Flood.	Shore quite clean.
Apr. 16	11:35	Foot 27th st. to end of Emmons ave., extreme east end Sheepshead bay.	N. W..	Flood.	Some seaweed. No sewage found along shore.
Apr. 16	1:10	Pumping station east end of town.	N.....	Flood.	Water in Sheepshead bay stirred up by dredger, filling in flats between bay and Manhattan Beach. Very little sewage detected in bay. Only slight scum at certain points. No odor. Sewage of Sheepshead Bay (town) is pumped to eastern extremity of town, east of race track, mixed with chlorinated lime, the liquid part discharged into Bull's Creek and the solid siphoned out onto the flats nearby. There was no odor where deodorized contents of deposit tanks were discharged April 14. There are oyster beds in Bull's Creek where liquid part of sewage empties.
Apr. 16	2:35	[South shore of Sheepshead bay from Coney Island creek to bridge.	N.....	Ebb...	Shore clean. Scum of sewage at one point near opening of creek.
Apr. 16	3:15	South shore from bridge to Oriental hotel.	N. W..	Ebb...	No sewage on water. Shore clean.
Apr. 16	3:55	Point east of Oriental hotel.	N. W..	Ebb...	Sewage from Manhattan Beach and Oriental hotels pumped to pumping station here, and after treatment with lime, emptied into New York bay, just outside of seawall.

On comparing table 22 with 18 it will be seen that both shores of the Lower Bay were polluted for a considerable distance from the Narrows. The Staten Island shore contained large quantities of garbage as far as the inspections were continued in that direction, that is, Midland Beach. The north shore of the Lower Bay was
fairly free from visible evidences of sewage and other pollu-
44 tion, except near the outlets of local sewers, where occasionally small amounts of sewage scum were seen floating at a considerable distance from the shore.

The presence in this vicinity of large grease balls which could only have been derived from sewers of considerable length, showed that some sewage was evidently transported to these shores from Brooklyn sewers which emptied into the Upper Bay.

That portion of the shore of the outer harbor which lies in the vicinity of Norton's Point contained so much driftwood, garbage and sewage matter that it seems reasonable to conclude that this point is a collecting center for refuse which flows out of the Narrows. As much as 5 cubic yards of animal and vegetable refuse were found on 400 square feet of beach in this vicinity. Men who were found gathering wood here said that the supply of fuel was inexhaustible.

From Norton's Point eastward there was a constantly diminishing amount of putrescible refuse until, about midway between the two ends of Coney Island, it was reduced to an occasional lot of garbage or a dead animal or so. The shores and water of Sheepshead Bay were fairly clean, as might be expected at this season of year.

Inspections confirmed what the chemical and bacteriological analyses of the commission had already shown concerning the objectionable practice of cultivating oysters in the creeks in the immediate vicinity of New York.

Bodine creek, on Staten Island, where large quantities of oysters are "drinked" in preparation for market was reported by the inspector to be obviously polluted with sewage. The shores were strewn with vegetable and animal matters and a scum of grease and
petroleum was on the water.

45 Equally objectionable conditions connected with the oyster industry were found elsewhere. The liquid part of the sewage of the town of Sheepshead Bay was found to be emptied, after being treated with chemicals, into Bull's creek in the immediate proximity of oyster beds.

The danger of polluting oysters in these ways was clearly pointed out in the first report of the New York Bay Pollution Commission. The existence of the resulting danger to the public health was em-

phasized by a typhoid oyster outbreak which occurred at Lawrence, N. Y., in 1904, and was investigated and reported on by me.

D—Conclusions.

The principal conclusions which it seems proper to draw from the foregoing investigations are in conformity with the conclusions recorded in the first report of the commission. They are as follows:

1. The waters of the bay and adjacent waters are unmistakably, but not as yet badly, polluted.

2. The sewage is not uniformly dispersed and diffused throughout the depth and breadth of the tidal currents. The discharge of crude sewage results in polluting the water more at the surface than in the depths below.

3. The discharge of sewage along the shores often leads to the production of a decided local nuisance.

4. Although the present method of disposing of the sewage of Manhattan is, perhaps, as acceptable as any method of emptying crude sewage into these waters could be, it is far from being always satisfactory.

5. The disposal of sewage at the pierhead line, as practiced on Manhattan Island is much to be preferred to the plan of
46 emptying it at the bulkhead line as is generally practiced elsewhere in this vicinity.

6. There is no doubt but that offensive matters from the sewage, and the sewage itself, are sometimes transported long distances by the tides and winds and deposited on shores remote from any sewer outlet.

7. Excepting in such heavily polluted waters as Gowanus Canal, there is probably always enough oxygen in the water to enable the bacteria of decomposition to carry on their work without the production of offensive odors.

8. No other method of disposing of the sewage of New York and vicinity is suggested as the result of these investigations. It is evident that some other method should be devised, if practicable, but the satisfactory study of this question involves investigations of a far more exhaustive character and of a wider scope than have thus far been possible.

47 I, George R. Van Namee, Clerk of the Assembly, do hereby certify that the aforegoing is a true and correct copy of Assembly Document No. 76 as filed at this office, being a Report of the New York Bay Pollution Commission of May 3rd, 1903, and of the whole thereof.

[Seal Clerk of Assembly, State of New York.]

GEORGE R. VAN NAMEE,
Clerk of the Assembly.

N.B. Gas works 9th - 13th Sts, 22nd St, 42nd St & 61st Sts. Samples taken in these slips were all black oily ooze with a strong odor of tar & illum. gas except #470 which was clay like consistency, color of terra cotta. When dry had no odor. Black ooze from several million bacteria per gram. That from 22nd St. where gas waste was plentiful only 170,000.

1 COMPLAINANTS' EXHIBIT No. 29. James D. Maher, Commissioner.

July 25, 1907.

Franklin Clarkin, Esq., Ass't Secretary City Club of New York, 55 West 44th St., New York City.

DEAR SIR: Referring to your communication of June 5th in which you ask for an opinion based upon the studies of this Commission on river pollution, whether the use of river water as it is, would be undesirable for sprinkling or flushing city streets, we beg to state we understand from this that your inquiry relates to the suitability of water taken from the Hudson or East River for use in sprinkling or flushing the streets of the Borough of Manhattan.

In such case an opinion must take into consideration the pollution of the water to be used as measured by the presence of decomposable organic matter and of bacteria capable of producing disease. These questions have engaged the serious attention of this Commission for a number of months and many hundreds of samples of river and bay water as well as muds deposited therein have been
2 carefully taken and subjected to chemical and biological analyses. The full conclusion to be drawn from this work would at this time be premature and improper. The weight of present evidence may however be stated to indicate strongly the probable inability of the waters of the East and Hudson Rivers and the Upper Bay to assimilate and destroy within a reasonable time the sewage wastes discharged therein. Some of the observations made would no doubt be of present interest to those who are giving the general subject their attention and without in any way emphasizing the relative importance of any particular observation this Commission is willing at this time to announce the results of a series of observations taken along a line projected from the Battery to Jersey Central Railroad Station on the New Jersey shore:—

Bacteria Per C. C. Hudson River Water, Feb. 20, 21, 1907.

Depth.	State of tide.	100′ from Pier "A."	500′ from Pier "A."	¼ way across.	Mid-stream.	¾ way across.	500′ from N. J. C. R.R. Sta.	100′ from N. J. C. R.R. Sta.

	Ebb....	7950	6350	3800	3500	3600	1900	3050
20′	Flood..	5200	5100	3800	3500	2850	4050	4750
	Ebb....	6350	5850	3500	3300	3300	5300	8500
40′	Flood..	4050	4550	2400	2400	2150	....	....
	Ebb....	4350	3900	2400	2500	2200	....	....
50′	Flood..	3800	2850	2350	....	....	....	....
	Ebb....	3800	4050	2150	2550	....	....	....

3 These matters relate to the general duties of the Commission in determining the sanitary condition of the waters as a whole rather than to the question raised by the City Club and in order that certain special information required by your inquiry might be available it was decided to make a brief investigation of the biological effect of sprinkling with river water surfaces exposed to the same influences of air, sunlight and shade as would be the City streets under the conditions which you mention. For this purpose samples of North River water were taken at the site of the floating baths at the Battery early in the morning before the baths were opened, the tide being flood about one-half (½) full, the wind southwest and moderate. Two samples A. and B. were taken 20 feet from the Battery Pier, A. being 1 ft. and B. at bottom 15 ft. below the surface. The temperature of the water was 15½ degrees C., the air being 27 degrees C. Both samples had eight points of turbidity, ten points color, about 12,000 parts per million of chlorine representing 2 & sodium chloride and a faint sewage odor. After 48 hours sample A showed 6350 bacteria per C. C. and sample B 4770. Both
4 gave a positive test for B. Coli (intestinal bacteria) in 24 hours.

A sample of sea water was taken from outside of Sandy Hook. This showed 0 points turbidity, 5 points color, 27,000 parts chlorine equivalent to 4.5% sodium chloride, no odor, no bacteria and negative test for B. Coli. A portion of sample A mixed with an equal portion of this sea water, showed after 48 hours 742 bacteria per c. c., while another portion of sample A mixed with an equal amount of distilled water containing 30% sodium chloride (saturated solution) gave after 48 hours only 104 bacteria per c. c. The results of this test indicate the bactericidal effect of relative strong solutions of salt.

Experiments on Samples of Street Dust.

Two samples of street dust were collected on sterile dishes.
A from spot always in sunlight.
B from spot always in shade.
Equal portions of each were added to 500 c. c., sterilized, distilled water and plated. Sample A shows 1,200,000 bacteria per gram and sample B 8,000,000. Both gave positive tests for B. Coli in 1 c. c. and .1 c. c.

Other equal portions of the two samples were then thoroughly wet with sample of river water before mentioned taken from depth 15 ft. The samples of wet dust were then divided, one half of each being places in sunlight and the other half in the shade. At
5 the end of six hours all were dry at which time portions of all were mixed with 500 c. c. sterilized distilled water and plated.

A	exposed in	sunlight	6	hours	showed	440000 bacteria per gram
A	"	" shade	6	"	"	800000
B	"	" sunlight	6	"	"	700000
B	"	" shade	6	"	"	3000000

showing again the bactericidal effect of salt water and the more pronounced bactericidal effect of sunlight. All the above platings showed positive tests for B. Coli in 1 c. c. also in .1 c. c. except samples exposed to sunlight.

Similar tests were made with samples of the dust when sprinkled with the pure strong sea water before referred to and with distilled water containing sodium chloride in saturation.

A	with pure sea water				5	hours	in shade	showed	636000	bacteria per gram
B	"	"	"	"	5	"	"	"	1400000	" "
A	"	saturated sol. nace.			5	hrs.	in shade	"	120000	" "
B	"	"	"	"	5	"	"	"	140000	" "

Confirming the greater bactericidal effect of salt in stronger solutions. All of the above platings showed positive tests for B. Coli in 1 c. c. and .1 c. c. except samples sprinkled with saturated solution of sodium chloride which gave negative tests in both case-.

6

Remarks.

The places and conditions of taking the samples of river water tested were most favorable as it is believed no purer water touches the shores of Manhattan Island than at the Battery during the strong flood of the tide. Although the tests showed conclusively that salt water and sunlight are somewhat inhibitive to the micro-organisms present in polluted water and in street dust it does not appear that the intestinal bacteria are destroyed by the water containing salt in quantities such as obtained in the river and harbor even when combined with exposure to sunlight for periods long enough to dry the dust containing these organisms.

The possible danger to public health from depositing the germs of disease known to exist in sewage wastes upon the streets whence they may be blown about when in a dry state, we do not believe has been sufficiently disposed of by the tests which we have made to permit us to assure you that the use of river water for flushing or sprinkling the City streets in its present state is desirable.

7

It is well known that typhoid bacillus will live from several hours to several days in a dry state depending upon the amount of exposure to the sun. Other bacteria which may be present in sewage polluted river water live for varying lengths of time after drying.

This Commission will continue the foregoing studies at other places along the river fronts of both the Hudson and East Rivers

where the pollution of the water is known to be greater than th samples heretofore tested and will be pleased to advise you furthe with respect to these studies should the results thereof tend in an way to modify the conclusions herein presented.

Yours very truly,

—— ——, *President.*

—— ——, *Secretary.*

COMPLAINANTS' EXHIBIT No. 30. James D. Maher, Commissioner.

Data Abstracted from the Results of the 705 Observations on Harbor Deposits—As Made by the Metropolitan Sewerage Commission Prior to 1908, and as Given in Complainant's Exhibit No. 14.

COMPLAINANTS' EXHIBIT No. 44. James D. Maher, Commissioner.

Float Observations.

October 26, 1908.

Dr. George A. Soper, President Metropolitan Sewerage Commission of N. Y., New York City.

DEAR SIR: I beg to report as follows results of float observations made in the Harlem River in August and September.

From the N. Y. C. & H. R. R. R. bridge at Spuyten Duyvil to a point nearly opposite East 125th St. the Harlem River is 6½ miles long. In round figures the different bridges are the following distances from the Spuyten Duyvil bridge:

Spuyten Duyvil	Bridge	0	mi.
Broadway (Kingsbridge)	"	1	"
University Heights (207th St.)	"	2	"

* Approximate only. This time was not observed.

† A velocity of 1.80 was also observed in this float in the Bronx Kills.

** North West of North Brothers Island.

3 The following statement comprises a summary of the principal facts regarding the float records as observed in the Harlem River.

NOTE.—Here and in the following discussion—

High Water at Governors Island is indicated by H W G I
and Low " " " " " " " " L W G I

From an inspection of this table the following inferences may be drawn, subject to modification with a greater number of records.

1. The flood current in the Harlem begins to run about an hour and a half after predicted L W G I.

2. The ebb current begins about an hour and a half after H W G I but progresses from the south end of the river northward as indicated by the following figures:

At 116th St..... 0 hr. 25m. after H W G I
" 122nd " ..... 1 " 15 " " "
" 131st " $\frac{1.10 + 1.30}{2}$ ..... 1 " 20 " " "
" 135th " ..... 1 " 25 " " "
" 139th " ..... 1 " 20 " " "
" 142nd " ..... 1 " 30 " " "
" 219th " ..... 1 " 45 " " "

3. The mean flood velocity appears to vary from ¾ mi. to 1¼ miles per hour, (1.1 to 1.8 ft. per sec.).

4. The mean ebb velocity approximates 1.4 miles per hour or 2.0 feet per second.

5. The maximum velocity varies with the cross-section of the channel, but in general it may be taken as about 2.35 miles
4 per hour or 3.45 feet per second on the ebb.*

On the flood a velocity of 2.35 was noted once, the other maxima falling below 2 mi. per hour, indicating an ordinary maximum less than that in the ebb current.

6. The path of float No. 3 represents the flow of an entire flood tide, that of float No. 5 nearly an entire flood tide, and that of No. 7 represents the flow of an entire ebb tide. The path of float No. 13 (ebb) extends the entire length of the Harlem under consideration (north of Bronx Kills), while those of Nos. 5 and 7 extend over

*See note page 4.

nearly all of this distance. Float No. 6 showed a strong current flowing to the east through Bronx Kills and Little Hell Gate; floats 11, 12 and 13 passed into and down the Hudson; while No. 14 would have turned back in the Harlem between the Washington and University Heights Bridge on the arrival of the flood current. The distances traversed in the Harlem are:

Float No.	Flood.	Ebb.
5	6.05	
7	4.70	
8	4.05	
13	.....	8.95
Average of all mean velocities observed	0.97	1.33

$$\frac{\text{Distance traversed on ebb}}{\text{Average distance traversed on flood}} = \frac{6.95}{4.93} = 1.41$$

$$\frac{\text{Average of mean ebb velocities}}{\text{Average of mean flood velocities}} = \frac{1.33}{0.97} = 1.37$$

5 NOTE.—Assuming the above figures as correct there follows:

$$\frac{\text{Mean veloc.}}{\text{Max. veloc.}} \quad \frac{2}{3.45} \quad 0.58$$

According to the zin curve.... $\left\{\frac{\text{Mean veloc.}}{\text{Max. veloc.}} \quad \frac{2}{} \quad 0.64\right.$

These figures indicate:

a. That the general trend of sewage discharged into the Harlem River is toward the Hudson River.

b. That the general progression in this direction is from one to two miles per tide.

c. That the preponderance of discharge into the Hudson River over that into the East River may be taken provisionally at 40 per cent.

d. That practically the entire contents of the Harlem River at the end of the flood pass into the Hudson River during the ebb and that over half the contents at the end of the ebb pass into the East River during the flood.

The duration of slack water on either tide is shown to be short by the records of floats Nos. 6, 7, 8, 11, 12 & 13, as a rule not exceeding about fifteen minutes.

Although affected somewhat by the wind (see floats Nos. 5, 7) and so in some instances driven toward the shore, there seems to be no general tendency in this direction. On the contrary it is probable that floating matter generally follows the channel of the stream,
and so finds a free exit to either the East or Hudson River.
6 The normal tidal current, however, is subject to variation, not only by the effect of the wind near the surface, but by the passage of vessels, the obstruction of piers and by the continual change in cross-section. In those reaches where the cross-section is constricted and the channel straight and uniform—as in the Ship Canal—a higher velocity will naturally obtain than where the opposite conditions are found.

The velocity of the float depends, not only on the above matters, but to a very considerable extent upon the part of the stream traversed. If near the shore the velocity may be greatly retarded. The mean and maximum velocities indicated by the floats are therefore likely to be less than the actual velocities they represent.

In Appendix 9 of the report of the U. S. C. & G. S. of 1888 the elevation of the Hudson at 42nd St. and of the East River at Pelhemus Dock are given for each lunar hour. The mean elevation in the Hudson for the entire period is 0.02 above the mean sea-level at Sandy Hook and that of the East River 0.20 below that datum the resultant elevation in the Hudson being 0.22 above that in the East River.

By scaling from automatic tide gage records of the Dock Department for 24 hours from 10 p. m. April 24, 1908, taken at 131st St. in the Hudson and at Astoria in the East River the differences are more marked, the mean elevation of the Hudson being 0.30 above that in the East River.

These results, arrived at from independent sources, would
7 lead one to expect a preponderance of flow from the Hudson through the Harlem to the East River.

By superimposng tide gage records taken simultaneously at 131st St. on the Hudson and Astoria on the East River it will be seen that the tide changes first in the Hudson and is of less amplitude than in the East River, also that the times of slack water in the Hudson River as observed by us occur very nearly at the times of equal elevation in the Hudson and East Rivers, indicating that the flow through the Harlem is truly "hydraulic" in character, that is, dependent in amount on the surface slope for its magnitude. For this

reason sewage discharged from the Harlem River is carried by the ebb toward the Sound in the East River and by the ebb down the Hudson and not in the reverse direction until the tide changes. The vertical distance between the two curves at any time represents the differences in elevation of the respective water surfaces at the time. It will also be observed that while this difference is greater during the flood tide the actual elevation of the surfaces is greater during the ebb. This last difference amounts to 0.67 by the above records and to 1.36 according to the figures contained in the U. S. C. & G. S. report above referred to. This means that during the ebb the cross-section of the water in the Harlem is greater than during the flood, tending to counteract the effect of the .2 or .3 higher average elevation of the Hudson. Then, too, the flood current is subject to a certain throttling in the constricted channel between Spuyten
8 Duyvil and Kingsbridge, while the entrance from near Randall's Island is more free and unobstructed. The relative values of these different factors it is impracticable to estimate owing to the irregular and variable character of the cross-section of the Harlem, and we must rely on the evidence of actual observations, as by floats, current meters, etc.

If we assume that the distance traversed by the flood current is 4.93 miles and that by the ebb is 6.95 miles, and if we take 12,600 sq. ft. as the mean cross-section of the Harlem River at mid tide,* the discharge into the East River during every flood tide is about 328 million cubic feet and that into the Hudson River 462 million cubic feet.

9 In view of the apparent anomaly of an excess of flow toward the stream having the higher average surface level the results of the small number of experiments by which this excess toward the Hudson is indicated should be confirmed by further observations before accepting them as final. On account of the narrow width of the Harlem, its obstruction by bridges, the interference of traffic, all of which interfere with the normal motion of a float, I recommend that a gauging of the stream be made to settle this question. To avoid the interference of traffic as much as possible, as well as the disturbance due to bridges, piers and other structures, such a gaging could best be undertaken toward the northern end of the stream, and a most favorable location would appear to be in the Harlem Ship Canal, where the channel is fairly uniform as to depth and width. In any plan adopted the necessity of avoiding interference with traffic has to be borne in mind.

To obtain the most reliable results expeditiously such a gaging should be done by the use of a current meter. If this plan is adopted

---

* An average of cross-section as scaled from the Coast Survey chart below the Broadway, High, Central and Park Avenue Bridges.

the stream should be cross-sectioned by soundings every 10 feet at the proposed location. The instrument can be operated from a launch anchored on a range line at right angles to the shore and located in position by observation from, or ranges set by, a transit at the end of a measured base on one shore. As the mean velocity is generally found at from 55 to 65% of the depth I would take the observations at a point 60% of the depth continuously or, at least, for 20 minutes each hour, for a complete cycle of the tide. By this method a complete integration of all the fluctuating velocities flowing water is subject to may be secured for each station on the desired cross-section, such stations being perhaps 50 feet apart, making zone 7 stations in all.

Such a series of observations would occupy 15 actual working days and is estimated to cost as follows, allowing one extra day for launch on account of bad weather:

Launch, Captain and one man,	at	$17.00 per day	$240.
Transit man	at	5.00 " "	70.
Observer	at	7.00 " "	98.
Current meter, material, etc.			175.
Cross-sectioning stream, etc.			42.
			$625.00

If a current meter could be borrowed this amount would be correspondingly reduced.

A somewhat simple though not so accurate a gaging may be made by timing the passage of vertical float rods between two cross-sections 100 or 200 feet apart. The reason this is not so accurate a method is, first, that the rod cannot be of such a length as to represent the mean velocity, secondly, that the rods will not float in parallel directions between the two cross-sections but will be influenced by local eddies and cross currents, and, thirdly, because the cross-section of the channel itself is constantly changing between the upper and lower cross-sections. However, it is believed that this method would furnish results that will not vary from the true gaging as much as any one gaging may vary from another made under other conditions, (of fresh water in the Hudson, phase of the moon, etc.)

With rods 12 ft. long weighted at the lower end, 7 starting points, and observations hourly from each point, the estimated cost would be, allowing for one day extra for launch on account of rain:

10 floats		at	$1.00.....	$10.
Launch and crew,	6 days	at	16.00.....	96.
Transitman	5 "	"	5.00.....	25.
Starter	5 "	"	4.00.....	20.
Man in rowboat to recover floats	5 "	"	2.00.....	10.
Preparatory instrumental work, cross-sectioning, etc.....				49.
Total.....				$210.

Very respectfully,

_____,

Chief Engineer.

COMPLAINANTS' EXHIBIT No. 51. James D. Maher, Commissioner.

Float Observations.

NEW YORK, November 19, 1908.

Dr. George A. Soper, President Metropolitan Sewerage Commission, New York City.

DEAR SIR: I beg to report as follows the results of float observations made by this Commission in the East River south of Hell Gate. The following are in round numbers the distances of important points from the north end of Governor's Island:

Brooklyn Bridge	1.3	miles.*
Manhattan "	1.6	"
Wallabout Channel	2.5	"
Williamsburgh Bridge	2.8	"
Newtown Creek	4.5	"
South end Blackwell's Is	5.5	"
North " " "	7.4	"
Mill Rocks and Hallet's Point	7.9	"

The accompanying table comprises a summary of the principal facts regarding observations on two floats made in 1907 and six floats in 1908 in this part of the East River, from which the following inferences may be drawn.

*In this discussion where the word "miles" occurs it is intended to mean "statute" miles and not "nautical" miles.

				Data Obtained.

* This float went aground and had to be set out again twice.

THE FLOATS OF THE STATE OF NEW YORK (S. 2270)

1 1. The ebb current may be expected to set:

	h m.		
Ebbing between Williamsburgh bridge and Newtown Creek at	1 25	after	H. W. G. I.
Ebbing between Newtown Creek and Blackwell's Island at	1 50	"	"
Southeast of Ward's Island	1 45	"	"

The turn of the tide indicated by Float No. 38 in Hell Gate just northeast of Hallet's Point 3 h. 10 m. after H. W. G. I. is difficult to explain and would indicate that the time of slack water is subject to a considerable variation in this vicinty. The moderate north wind blowing at this time would not account for such a difference between the times noted here and those at other points.

2. The mean velocity of the flood may be taken as 2 miles per hour (3 ft. per sec.).

3. The mean velocity of the ebb may be taken provisionally at 2.8 miles per hour (4 ft. per sec.), this being an average of five ebb reads extending over 7 miles in length, but as these vary from 2.16 to 3.70 miles per hour it may be that the velocity depends to a large degree upon the part of the channel traversed.

4. The maximum flood current is for short intervals and certain localities at least 6.8 miles per hour (10 ft. per sec.), but for any considerable distance and interval probably 4 miles per hour (6 ft. per sec.) would be a fair and usual figure.

5. The maximum ebb current noted was 8.57 miles per hour (12½ ft. per sec.) in approaching the channel west of Blackwell's Island from the north. For any considerable distance and interval 6 miles per hour (9 ft. per sec.) would probably be nearer the truth.

4 On account of the high velocities prevailing in this part of the East River the time taken to traverse the 7 or 8 miles is less than a complete ebb or flood tide as shown in the following figures:

Float (Mar. 7, 1907),	covered	8	miles	in	4h.	47m.	of	flood.
" No. 38	"	5.64	"	"	2h.	47m.	"	"
" No. 39	"	5.36	"	"	2h.	37m.	"	"
Float (Mar. 29, 1907),	covered	8.8	miles	in	2h.	50m.	of	ebb.
" No. 10	"	9.7	"	"	4h.	30m.	"	"
" No. 23	"	7.68	"	"	2h.	5m.	"	"
" No. 38	"	7.42	"	"	3h.	25m.	"	"

This renders it impossible to arrive at precise figures for the mean velocity of the flood or ebb current or for the discharge of the stream at each tide. It is probable that owing to the fact that the flow is "hydraulic" or directly dependent upon the difference in head between Willet's Point and Governor's Island, the velocity and discharge vary to a considerable extent from the influence of the winds on the tidal elevations at those points.

We may be reasonably justified, however, in concluding from the results shown above and by reference to the plotted paths of the floats:

a. That there is a predominance of discharge to the harbor from Long Island Sound through the East River.

b. That, on account of the high mean velocities a volume equivalent to the contents of the East River south of Hell Gate passes out at each tide, that is, four times a day. It should be remembered, however, that the greater part of this water so discharged enters again on the following return of the tide.

c. That while the bulk of the sewage contained in the East River at the beginning of the flood current will find its way to the east of Hell Gate it is not likely to go far in this direction, but will eventually pass to the southward and through the Narrows to the ocean.

d. That the trend of the flood current may take the contents of the lower East River past the eastern channel at Blackwell's Island (Float 38), but that the main current from Hell Gate south passes through the western channel. (Floats of March 29 and Nos. 10, 16 and 38).

e. That the ebb current may pass to the west (Floats of March 29 and No. 23) or to the east (Floats Nos. 27 and 38) of Governor's Island.

f. That the duration of slack water is very brief (Floats Nos. 10, 27, 38).

g. That on account of the velocities, the predominance in one direction and the brief periods of slack water the bed of the East River south of Hell Gate is kept well scoured and free from extensive deposits except near the piers.

h. That there is an apparent tendency for floating matter to work in toward the Brooklyn shore on the flood current (Floats of March 7th and Nos. 10 and 38). It is possible that this is due in part to the wind, but the tendency is not shown by the ebb records.

NOTE.—The records of Float No. 38 is of particular interest as showing the nearly continuous path of the float during a complete cycle of the tidal flow. It was set adrift in the middle of the west channel opposite the north end of Blackwell's Island at 3.02 A. M. By 3.55 A. M. it had drifted ¾ mile into Hell Gate northeast of Hallet's Point. Here the ebb flow began, carrying it to 200 ft. south of Mill Rocks by 4.07 A. M., thence, with velocities increasing to 4½ miles per hour, by the channel west of Blackwell's Island and then following the middle of the river to the south side of 6 Wallabout bay by 6.38 A. M. From here it followed the eastern side of the river to the Manhattan bridge passing over 1,000 feet in 2 minutes (5.7 mi. per hour—its maximum velocity), 2,165 ft. in 6 minutes (4.1 mi. per hour) and 3,115 ft. in 8 minutes (4.4 miles per hour). From here the path swerved toward the center of the river and at 7.12 A. M. the float was 1,000 feet northeast of Governor's Island and had traversed the last 2.62 miles in 40 minutes, or at a rate of 3.93 miles per hour. Passing down the west side of Buttermilk Channel the float reached a point 1.2 miles south of Governor's Island and about a mile west of the pier head line just south of Gowanus Canal at 8.44 A. M. Here, due in part to a strong west wind, at slack tide, the float drifted ¾ mile toward the shore with a velocity of about 2 miles per hour and then at 9.37 A. M. turned northerly on the flood current. This, with the wind, carried it up the Buttermilk Channel close to the pierhead line with velocities increasing quite uniformly to 2 miles per hour by 12.47 P. M., when it reached the Brooklyn bridge. Between this point and the Atlantic Basin (11.55 A. M.) it had run ashore five times and had been reset from 100 feet to 300 feet out. At the Brooklyn bridge it was reset about 750 feet from the east pier and from here traversed 1.45 miles in 20 minutes or at the rate of 4.35 miles per hour, the maximum velocity of 6.8 miles per hour occurring in a distance of .34 miles opposite the Wallabout Basin. Here the float crossed from the west to the east side of the river which it followed until past Newtown Creek at 1.54 P. M. From here it swerved toward midstream but passed up the east channel close to the Blackwell's Island shore, reversing its direction sharply with the turn of the tide at 3.34 P. M. 1.35 miles below its position at the beginning of the previous ebb flow, and ¾ mile above the Blackwell's Island bridge, which it

reached again on the ebb current at 4.18 P. M. The total distance traveled was 20.4 miles in 13 hours 16 minutes. Of this 10.39 miles were traversed on the ebb in 5 hours 42 minutes at a mean velocity of 1.82 miles per hour, and 9.11 miles were traversed on the flood in 5 hours 54 minutes at a mean velocity of 1.54 miles per hour.

Respectfully submitted,
(Signed) KENNETH ALLEN.

1 COMPLAINANTS' EXHIBIT No. 57. James D. Maher, Commissioner.

Float Observations.

Copy.

NOVEMBER 9, 1908.

Dr. George A. Soper, President Metropolitan Sewerage Commission, New York City.

DEAR SIR: I beg to report as follows the results of float observations made in the East River between Hell Gate and Long Island Sound during August and september.

This portion of the East River receives from the west the waters of the lower portion of the East River and the Harlem River through Hell Gate, Little Hell Gate and Bronx Kills—three channels formed by Ward's and Randall's Islands: and from the east the waters of Long Island Sound.

From a point in the East River at the south end of the Harlem, between Hallet's Point and Mill Rocks, the distances to prominent points in the East River toward Long Island Sound are:

Mill Rocks and Hallet's Point	0	mi.*
Sunken Meadow	1¾	"
North & South Brother's Islands	2¾	"
North End of Riker's Island	3¼	"
Hunt's Point	4⅛	"
College Point	5⅛	"
Closson Point	5⅝	"
Tallman Point	5⅞	"
Old Ferry Point	6½	"
Whitestone Point	6¾	"
Between Ft. Schuyler & Willet's Pt.	8¾	"

*In this discussion, wheree the word "miles" occurs it is intended to mean "statute" miles and not "nautical" miles.

* Not observed. **1 h. 45 m. for Float No. 14.

The principal data resulting from float observations in this vicinity are comprised in the attached table.

The small number of float records taken in this part of the East River do not warrant very positive statements as to the results. The presence of Islands near the western end with the influence of the currents to or from the Harlem River render the hydraulic phenomena here complicated and constantly varying, while the tortuous paths of the floats indicate the absence of any one main channel which conveys at all times the greater part of the discharge. An inspection of the Coast Survey Chart shows, as we might expect, no well defined narrow channel but a waterway varying from about 30 to over 100 feet in depth, extending almost from shore to shore between Throg's Neck (Ft. Schuyler) and College Point. Here shoals to the east of Riker's Island split the westward current which becomes further divided in its approach to the Manhattan shore, and the contracted, rocky and shallow channels through Hell Gate, Little Hell Gate and Bronx Kills cause an increase in slope and velocity of the water surface at times of the strength of tide.

We may, however, draw the following inferences from an inspection of the data secured.

1. The beginning of the ebb current occurs about two hours later than at Governor's Island. According to the observations it begins earlier at Throg's Neck than at Hallet's Point, being 2 hrs. 15 mins. after H. W. G. I. between Sanford's Point and Riker's Island, 2 hrs. 45 min. off Whitestone Point, 1 hr. 50 min. near Thorg's Neck and about one hour one half mile N. E. of Throg's Neck.

2. The mean velocity is probably about 1.2 miles per hour for a full tide but this varies with the location.

3. The maximum velocity varies yet more with the characteristics of the channel. On the flood, 4.0 miles per hour was noted just east of Little Hell Gate and 3.6 mi. per hr. north of Riker's Island, while to the east of this two miles per hour appears to be a more nearly correct figure.

On the ebb 5.0 miles per hour was found in the narrows channel east of Ward's Island, and 2.18 mi. per hr. was noted west of Riker's Island, but east of this the maximum observed velocity—between Whitestone Point and Tallman Island—was only 1.37 mi. per hr.

4. The record of float No. 25, which was set adrift 2 h. 15 m. after H. W. G. I. and taken out 1 h. 43 m. after L. W. G. I. practically comprises a complete ebb tide. The distance traversed was 6.85 miles.

* Not observed. ** 1 h. 45 m. for Float No. 14.

Float No. 18, which was observed from 3 hrs. 7 m. after H. W. G. I. to the time of the tide at 1 hr. 43 m. after L. W. G. I. is the longest flood record, covering 4.41 miles.

Considering these two records only, the mean velocity during the ebb is 1.2 mi. per hour or 33½% greater than the 0.9 mi. per hr. noted during the flood, while the maximum velocity of 2.08 miles on the ebb exceeds the 1.98 observed on the flood by 5%. These figures mean little, however, owing to the irregular character of the currents, as already explained, but confirm in a slight degree the general opinion that there is an excess of flow from the sound into and down the East River.

5 Aside from the data contained in the foregoing table the paths taken by floats Nos. 2, 6 and 9 west of Randall's and Ward's Islands show the general trend of the currents at certain stages of the tide in this vicinity, where the current of the Harlem joins those of the eastern and southern reaches of the East River.

Float No. 2 was set adrift west of Little Hell Gate 44 minutes before H. W. G. I. and in 26 minutes traversed about 350 ft. toward the entrance to Little Hell Gate. At this period of the tide the Harlem River above Bronx Kills and the East River at Hallet's Point were presumably both in ebb, and the float would have passed Ward's Island on the north and east and thence gone down the East River.

About a quarter of an hour before H. W. G. I. the float was set adrift a little north of the previous point, and in 11 minutes traversed 300 ft. in a southerly direction, and if left would have continued down the East River west of Ward's Island or else by way of Little Hell Gate until the turn of the tide.

A quarter of an hour after H. W. G. I. it was again set out on the west side of the river west of the House of Refuge on Randall's Island, and, after curving to the south and east, at about 35 minutes after H. W. G. I., began moving to the north. Again at about 1 hr. 50 m. after H. W. G. I., when near 700 ft. from its starting point, its motion was reversed and in an hour and 40 minutes had passed its previous most southerly point. The ebb or northerly flow probably began in the Harlem a short distance north of this 20 or 30 minutes before the last reversal of float's motion. It appears, therefore, that the tidal currents of the Harlem and lower East River meet in the vicinity of Randall's Island.

6 Float No. 6 was set adrift at various points above and west of Randall's Island between 3 hrs. 5m. and 4 hrs. 44 m. after L. W. G. I. Both the Harlem and East River being in flood there was a marked tendency to pass to the south and then eastward through the Bronx Kills and Little Hell Gate. Set adrift a little south of Little Hell Gate and on the west side of the River the trend was northeasterly toward Little Hell Gate, which the float would have gone through on its way toward the Sound.

Float No. 9 was set adrift a little south of the entrance to Little Hell Gate about an hour before L. W. G. I., the Harlem and East River being in ebb. After going in a southerly direction for some 1,500 ft. its course was reversed at 5 minutes after L. W. G. I. Set adrift again it took a southerly direction again which was reversed at 50 minutes after L. W. G. I. The Harlem and East Rivers both being in ebb the influence of the Harlem appears to have been greater, although the northerly trend may have been influenced by a light southerly wind.

Passing to just above the entrance to Bronx Kills the float reversed its direction to the south 4 hrs. after L. W. G. I., again to the north at 5 hrs. L. W. G. I., and again to the south at 5 hrs. 50 m. after L. W. G. I. During this time the Harlem and East Rivers were in flood and the erratic motions of the float indicate the attempt of the two currents meeting here to secure a condition of equilibrium.

From a consideration of the above facts regarding these portions of the East River we may infer:

7 *a.* That sewage discharged in the deep water east of Riker's Island would not follow any well defined course but would be influenced by the existing and variable currents and winds. In many locations, especially in the bays and near the shores, deposits would be likely to occur.

b. Sewage finding its way to the shallower waters of Hell Gate, Little Hell Gate and Bronx Kills would in general be swept by the rapid tidal currents either to the Sound or to the East River.

c. Owing to the uncertain currents and low velocities in the Harlem between Hell Gate and Bronx Kills and from the fact that there is no positive and periodical current of any magnitude passing between the East River east of Hell Gate and the Harlem River, this

part of the River is not considered as favorable for the reception of large volumes of sewage. Such as may be discharged here may find its way either to the Hudson, to New York harbor or, possibly, to Long Island Sound.

Respectfully submitted,

KENNETH ALLEN,
Chief Engineer.

1 COMPLAINANTS' EXHIBIT No. 67. James D. Maher, Commissioner.

Copy.

Float Observations.

February 18, 1909.

Dr. George A. Soper, President Metropolitan Sewerage Commission, New York City.

DEAR SIR: I beg to report as follows the results of the observations of floats set adrift in the Upper Bay near the proposed outlet of the Passaic Valley sewer, which is, roughly, some 700 feet easterly from the Robbins Reef bellbuoy as scaled from a map in the last report of the Passaic Valley Sewerage Commissioners. This point is distant from:

The Battery	3.8	miles.*
Statue of Liberty	2.4	"
Bay Ridge	1.7	"
The Narrows	3.5	"
St. George ferry slip	1.0	"
Constable Hook	1.5	"

*In this discussion when the word "miles" occurs it is intended to mean "statute" and not "nautical" miles.

The following tables comprise a summary of the principal facts as regards the paths taken by 6 floats set out in 1907 and 9 in 1908.

2 From these results the following inferences may be drawn:

(1) In the vicinity of the proposed Passaic Valley sewer outlet, which will be referred to, for convenience, as Robbins Reef, the flood current is running to the west, up the Kill van Kull, at about 2 hours after L. W. G. I., (Float #28), and in a northerly direction shortly after this time (Float of March 5, 1907*) until 2 hrs. after H. W. G. I. (Float #32). A southerly (ebb) current may be expected here at other times.

(2) The extreme points reached during a single tide were, in the:

						Float No.
Kill van Kull, Shooters Island—a distance of	5.27	mi. in	4 h.	38 m...		28
Hudson River, 60th St., Manhattan— "	9.14	"	6 h.	18 m...		34
Upper Bay—E. side, Red Hook— "	2.78	"	3 h.	23 m...		35†
Lower Bay—From 2¾ mi. S. E. to— "	11.50	"	6 h.	0 m...	2/26/07	
2 mi. S. W. of West Bank Light— "	11.25	"	6 h.	30 m...	7/ 9/07	

*It is possible that this float would have been influenced more by a westerly current up the Kill van Kull if it had not been set out ¾ N. E. of Robbins Reef, and if a moderate S. W. wind had not been blowing.

†No float went up the East River. Float #35, evidently influenced by a strong west wind, might have done so if set out earlier.

3 Velocities observed near the location of the proposed outlet of the Passaic Valley sewer were as follows:

Time after H. W. G. I.	Float.	Current.	Veloc. Ft. per Sec.
1 h. 20 m.	No. 32	Flood	1.2
2 h. 30 m.	" 31	Ebb	0.6
2 h. 50 m.	3/4/07	"	2.2
3 h. 0 m.	6/25/07	"	3.7
3 h. 20 m.	No. 37	"	0.2
3 h. 40 m.	7/8/07	"	2.5
3 h. 50 m.	2/26/07	"	2.2
3 h. 50 m.	7/9/07	"	2.2
5 h. 45 m.	No. 30	"	2.8
Time after L. W. G. I.			
0 h. 40 m.	No. 29	"	2.6
2 h. 0 m.	No. 26	"	2.1
3 h. 0 m.	3/8/07	Flood	1.5
4 h. 0 m.	No. 34	"	1.9
4 h. 15 m.	No. 37	"	0.3
4 h. 30 m.	No. 35	"	0.7
5 h. 0 m.	No. 33	"	1.7

The above figures indicate velocities varying from 0.3 ft. to 1.9 ft. per sec. on flood currents and from 0.2 to 3.7 ft. per sec. on ebb currents. The low value of .2 ft. per sec. coming 3 h. 20 m. after H. W. G. I. and 0.3 with the same float 4 h. 15 m. after L. W. G. I. indicates a considerable variation in the velocities that may occur at any given time. It is evident that at times the velocity of the current would not prevent deposition of sludge, while at other
4 times a good scouring action would obtain, more particularly on the ebb, where the velocities are seen to exceed those on flood currents.

As to the mean and maximum velocities at other points the data given indicate that during flood currents:

1. A mean velocity of about 1.7 mi. per hour may obtain in Kill van Kull.

2. Mean velocities of from 0.8 to 1.45 may occur at points between Robbins Reef and the Hudson opposite 60th St.

3. A maximum velocity of 2.6 mi. per hr. may obtain in Kill van Kull.

4. Maximum velocities of from 1.5 to 1.65 may be expected at points between Robbins Reef and a point in the Hudson River 6 miles to the north (near Christopher St.)

and that during the ebb currents:

1. Mean velocities of from 1.2 to 1.9 mi. per hr. may be expected.

2. Maximum velocities will be found varying from 2 to 4.25 mi. per hour. The maximum velocities appear to increase from Robbins Reef to the Narrows, as would be expected on account of the constricted section, or possibly below, 3.14 mi. per hour being noted in the case of Float #32 nearly as far south as Hoffman Island.

The values given depend, of course, upon the location, the winds

** ebb current in 11 minutes.
" " 46 "

and the land water flow from the Hudson, any one of which may exert a marked influence on the velocity of the current.

An examination of the plotted paths of these floats show- a tendency in many cases to hug the shore—of Jersey City in the case of No. 34; of Brooklyn in the case of #35; of Manhattan in the case of No. 37; of Staten Island above the Narrows in the case of the floats of 2/26/07, 3/4/07, 7/8/07 and Nos. 29 and 32, and of Staten Island below the Narrows in the case of the float of 6/26/07 and No. 31. It is noted, also, that at the turn of the tide the path described is in nearly every case (Floats of 3/8/07 and Nos. 29, 30, 32, 33, 34 and 37) counter-clockwise, or to the left. The exceptions are in the case of floats No. 31, close to the Staten Island shore, and No. 35, which may have been influenced by a strong west wind. This phenomenon is confirmed by the statement of Mr. Jacob Walker, salinometer observer, Robbins Reef, who states that

at high water the current sets N. N. W.
at mid-ebb " " " S. E.
at low water " " " S. S. W.
at mid-flood " " " W.

It is probable that times of slack water will vary in the Hudson and Upper Bay with the volume of land water passing out but the observed times have been, in round numbers, as follows:

Float No.	Location.	Slack High Water.
34	West side of Hudson opp. 60th St.....	4 h. 10 m. after H. W. G. I.
3/ 5/07	East " " " " 54th "	2 h. 45 m. " "
37	East " " " " Bank "	3 h. 50 m. " "
33	0.6 mi. N. E. of Liberty Island.....	2 h. 50 m. " "
35	Off Red Hook.....	1 h. 35 m. " "

Float No.	Location.	Slack Low Water.
28	½ mi. S. of Robbins Reef.....	1 h. 55 m.
37	" " " "	3 h. 55 m.
29	2 " S. E. " "	3 h. 15 m.
30	Canal St. Pier—Stapleton.....	2 h. 0 m.
31	South Beach, S. I.....	1 h. 0 m.
7/ 8/07	½ mi. S. E. of Hoffman Id.....	1 h. 05 m.
2/26/07	2¾ mi. S. E. of West Bank Light.....	2 h. 35 m.
7/ 9/07	1½ " S. " " "	3 h. 20 m.

These results, obtained from so limited a series of observations, appear so erratic that no safe conclusions can be drawn from them except to emphasize the fact the times of slack water are subject to considerable variation.

Another curious action of the floats observed is in the curve described near West Bank Light and near the end of the ebb by the float of 2/26/07 to the east with a southerly wind and by that of 3/4/07 to the east with a northerly wind, while the float of 7/9/07 describes a curve toward the west in spite of a westerly wind.

(Here follows paster, marked page 7.)

Finally it may be said, in general:

(*a*) That sewage if discharged at the proposed outfall near Robbins Reef might for short periods of the tide be carried up the Kill van Kull as far as Shooters Island but with currents that would prevent much deposition unless near the shores.

(*b*) That it might reach as far north in the Hudson as 60th St.

(*c*) That, with a strong westerly wind it might be carried
8 to Red Hook or possibly into the East River and then return along the Brooklyn shore.

(*d*) That the ebb current would carry it below the Narrows and at times as far as Romer Shoal.

(*e*) That if the bottom velocities at the outlet are similar to those near the surface, they would not at all times prevent the formation of deposits, but with fine screening and sedimentation the periodical maximum tidal currents would probably remove the greater part of such deposits.

(*f*) That there appears to be a tendency for the currents from Robbins Reef to follow the shores.

Respectfully submitted,

(Signed) KENNETH ALLEN,
Chief Engineer.

Float Observations.

February 13, 1909.

Dr. George A. Soper, President Metropolitan Sewerage Commission, New York City.

DEAR SIR: I beg to supplement my report of November 19, 1908, on float observations in the East River south of Hell Gate with the following notes concerning Float No. 36 which had not been plotted at that time:

Float No. 36, September 30, 1908.

L. W. G. I. 420 A. M. H. W. G. I. 10.30 A. M

	Flood record.	Ebb record.
Start—No. mi. from N. end of Governors Id	0.65 miles	10.34 miles
Time after	LWGI—3h., 22m.	HWGI—2h., 10m.
Miles traversed	9.69 miles	4.55 miles
Time consumed	4h., 52m.	2h., 30m.
Mean vel.—mi. per hour	2.09	1.82
Max. " " " "	4.30	6.00
Where max. occurred—mi. from N. end of Governors Is	5.0	6.7
Beginning of Ebb current—Time after HWGI*	.....	2h., 10m.
Mi. from N. end of Governors Id	.....	10.65

*After 14 minutes of slack water.

2 Comparing these figures with those deduced from the floats considered in my reports of Nov. 19* and (with reference to the time of slack high water) of Nov. 9*, the conclusions then reached appear to be confirmed except that the maximum velocities noted with float No. 36 are somewhat less than with those previously noted: 4.3 in place of 6.8 in the case of flood currents and 6.0 in place of 9.0 mi. per hr. (9.0 to 6.0 being given as the probable range). I do not attach great importance to this variation; 1st, because the records are too few in number to draw definite conclusions as to the maximum velocity; 2nd, because the records of float No. 36 cover but a part of a tide—about 5 hrs. of the flood and 2½ hrs. of the ebb; 3rd, because the maximum velocity depends on the

*See page 2 of that report.

relation of tidal levels as affected by the winds in the bay and in Long Island Sound; and 4th, because it depends on the cross-section of the stream, which varies greatly in this stream:

Float No. 36 traversed 9.69 miles in 4 h. 52 m. of flood and 4.53 miles in 2 h. 30 m. of ebb. This is the longest flood record in the lower East River and it is noted that the longest ebb record (Float No. 10) covered 9.7 miles in 4 h. 30 m., the mean velocity being 2.16 mi. per hour, while on the flood float No. 36 made an average of 2.09 mi. per hr., indicating no great preponderance of flow in either direction.

The record of float No. 36 confirms the opinion that the trend of westerly currents through Hell Gate is down the westerly side of Blackwell's Island, and show that the flood current may also tend
to pass through this channel, although (Float No. 38) this
3 is not always the case.

The duration of slack water south of North Brother's Island was 14 minutes.

The tendency of the flood current to hug the Brooklyn shore is confirmed. In this case, in spite of a "moderate" to "strong" northeast wind, the float drifted into three slips between Wallabout Bay and Newtown Creek and had to be re-set.

Respectfully submitted,

(Signed) KENNETH ALLEN,
Chief Engineer.

BRIEF REPORT ON THE TIDAL ACTIONS

IN THE HARBOR OF NEW YORK

by

H. de B. Parsons.

18th December, 1911.

H. DE B. PARSONS,
71 WILLIAM STREET,
NEW YORK

BRIEF REPORT ON THE TIDAL ACTIONS
IN THE HARBOR OF NEW YORK
by
H. de B. Parsons.

It is difficult to clearly and concisely describe the tidal actions of the water in the Harbor of New York, because the movements of the water are not synchronous in all parts of the harbor. The salient features, however, are contained in this report.

The durations of slack-water are not the same in all parts of the harbor, nor does the current change at the same time in all parts of a section. The slack-water periods are included in the duration of the currents which add to 12 lunar hours.

CURRENTS AT EACH LUNAR HOUR.

The currents which exist in the harbor at each lunar hour of a tidal cycle are given below. The directions of the currents were chiefly obtained from the float experiments of the Metropolitan Sewerage Commission and from curves given on Figure Other observations were also made for purposes of verification.

One lunar hour equals 1.03508 solar hours.

At Governer's Island, high-water occurs 6 hours and 4 minutes (solar) after transit of moon. Low-water, 2 hours and 9 minutes (solar) after transit.

I Lunar Hour. The water is flowing out of the Upper Bay through the Narrows, toward the sea; into the Upper Bay through the Kill van Kull, the East River and the Hudson River; and the water level in the Upper Bay is falling.

II Lunar Hour. The water is flowing out of the Upper Bay, through the Narrows, toward the Sea; flowing into the Upper Bay through the East River and the Hudson River; the Kill van Kull is nearly slack; and the water in the Upper Bay at about mean low-water.

III Lunar Hour. The water is flowing out of the Upper Bay, through the Narrows toward the sea; out of the Upper Bay through the Kill van Kull, flowing into the Upper Bay through the East River and the Hudson River; and the water in the Upper Bay is rising.

IV Lunar Hour. The water is flowing into the Upper Bay, through the Narrows, from the sea; into the Upper Bay from the Hudson River; out of the Upper Bay and Hudson River into the East River; out of the Upper Bay into the Kill van Kull; and the water in the Bay is rising.

V Lunar Hour. The water is flowing into the Upper Bay, through the Narrows, from the sea; the Hudson River is nearly slack; flowing out of the Upper Bay through the East River and the Kill van Kull; and the water in the Bay is rising.

VI Lunar Hour. The water is flowing into the Upper Bay, through the Narrows, from the sea; flowing out of the Upper Bay through the Hudson River, East River and Kill van Kull, and the water in the Bay is rising.

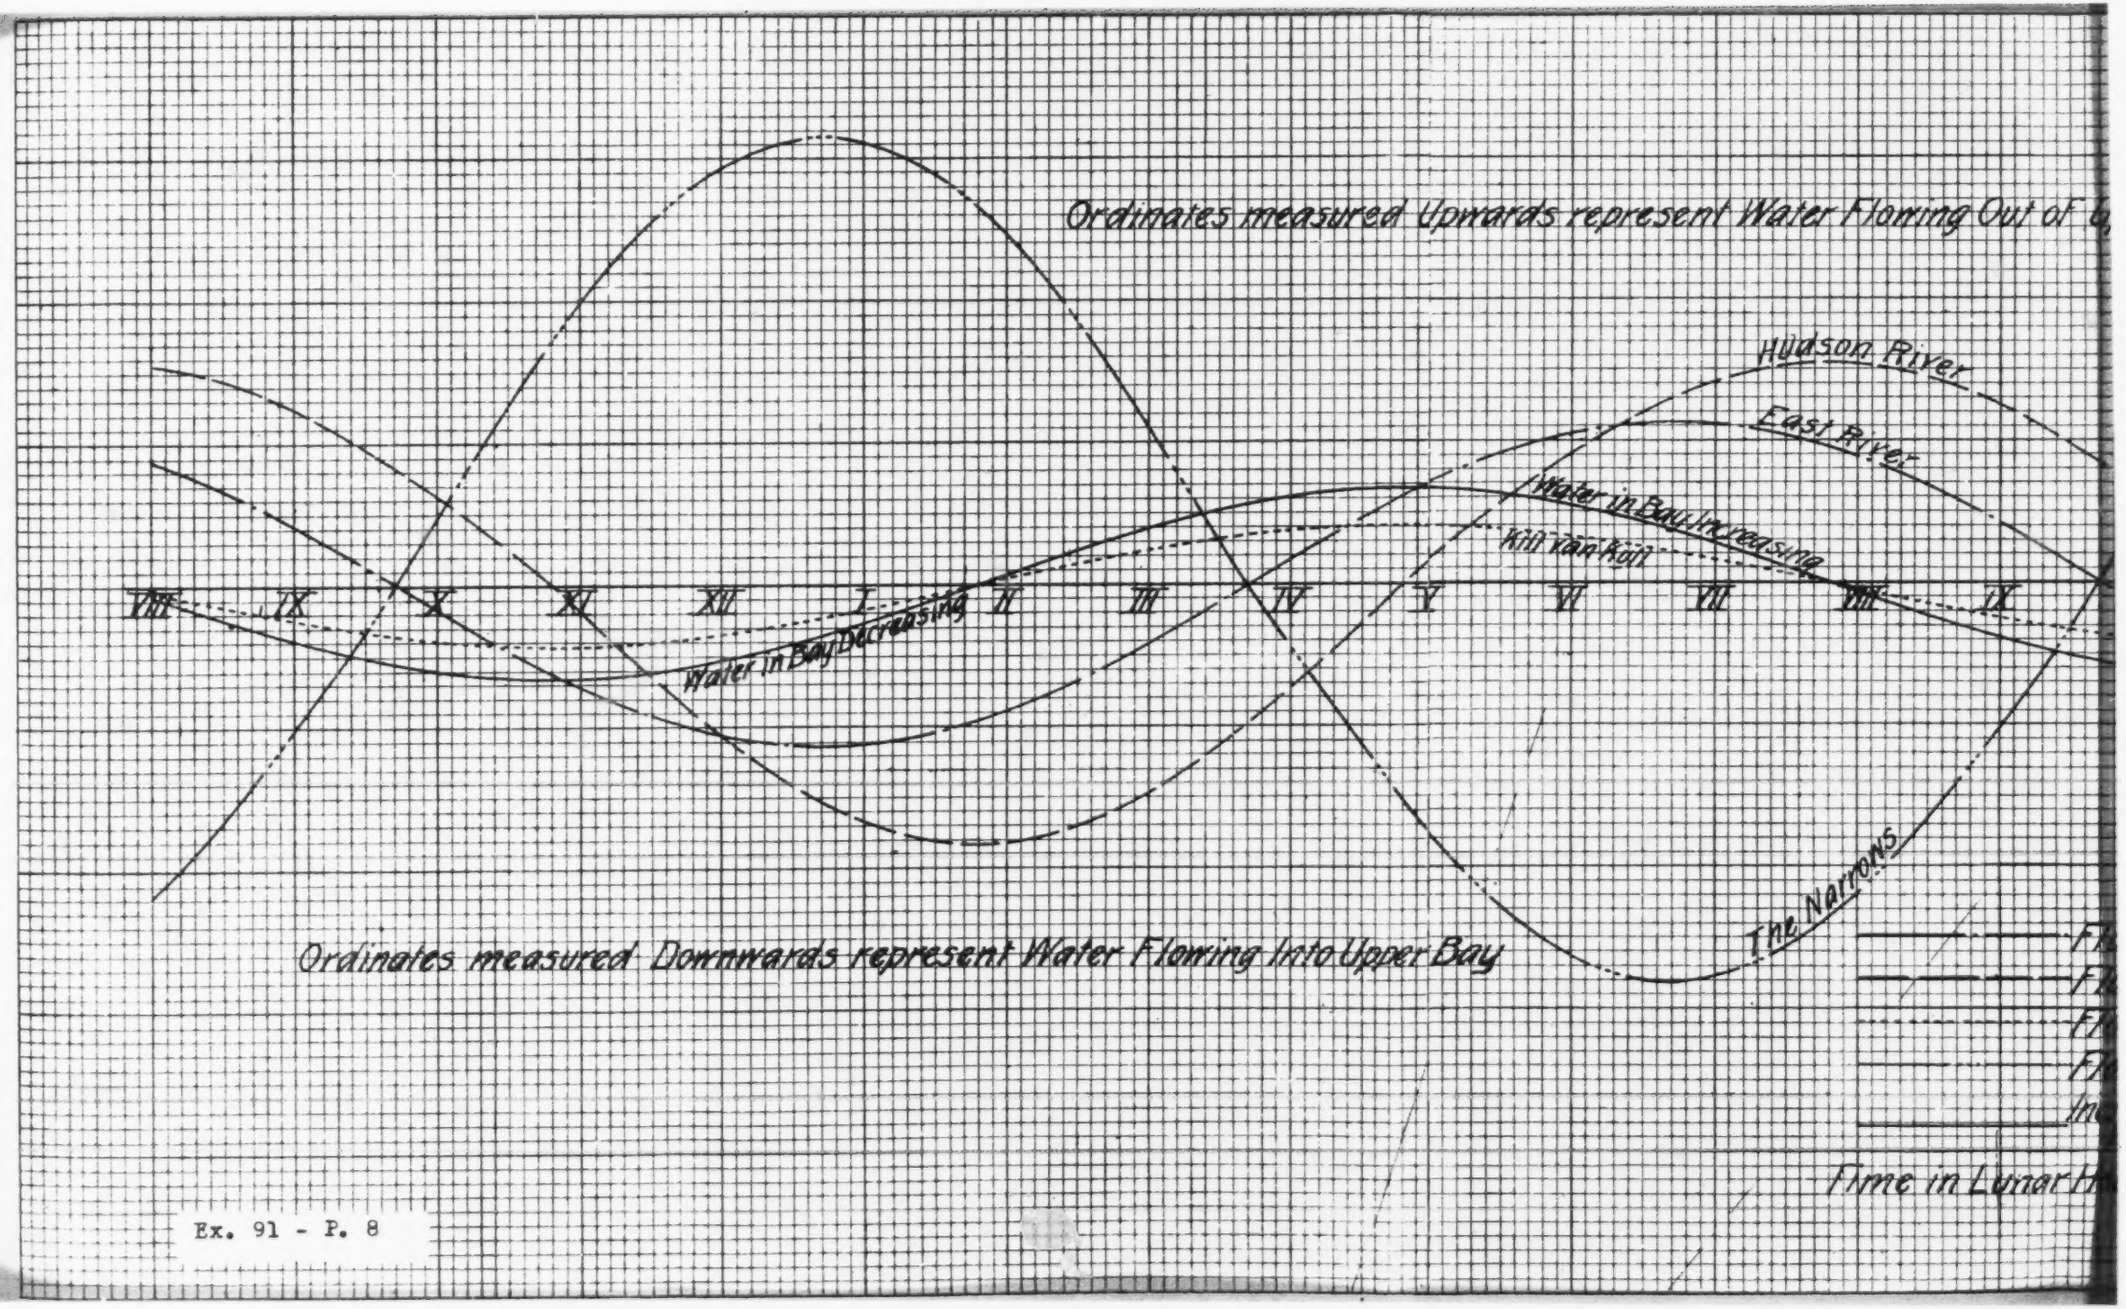
VII Lunar Hour. The water is flowing into the Upper Bay, through the Narrows, from the sea; flowing out of the Upper Bay through the Hudson River, East River, and Kill van Kull; and the water in the Bay is rising.

VIII Lunar Hour. The water is flowing into the Upper Bay, through the Narrows, from the sea; flowing out of the Upper Bay through the East River and the Hudson River; the Kill van Kull is nearly slack; and the water in the Bay is at about mean high water.

IX Lunar Hour. The water is flowing into the Upper Bay, through the Narrows, from the sea, and through the Kill van Kull; flowing out of the Upper Bay through the Hudson River and the East River; and the water in the Bay is falling.

I Lunar Hour. The water is flowing out of the Upper Bay, through the Narrows, toward the sea; out of the Upper Bay, and the East River through the Hudson River; into the Upper Bay and Hudson River through the East River; into the Upper Bay through the Kill van Kull; and the water in the Bay is falling.

II Lunar Hour. The water is flowing out of the Upper Bay, through the Narrows, toward the sea; the Hudson River is nearly slack; flowing into the Upper Bay through the East River and the Kill van Kull; and the water in the Bay is falling.



III Lunar Hour. The water is flowing out of the Upper Bay, through the Narrows, toward the sea; into the Upper Bay through the Hudson River, East River and Kill van Kull; and the water in the Bay is falling.

TIDAL VOLUMES.

Estimates of the volumes flowing on the tides past various sections of the harbor were made, chiefly based on investigations of the Metropolitan Sewerage Commission. These estimates agree with those of the U. S. Coast and Geodetic Survey.

Average Volumes in Million Cubic Feet.

	Ebb.	Flood.	Resultant.
The Narrows	12,041.2	10,778.8	1,262.4
Hudson River, West 39th Street	6,990.6	5,903.4	1,087.2
East River, Brooklyn Bridge	4,370.0	4,290.0	80.0
Kill van Kull, New Brighton	1,644.1	1,555.9	88.2

Ex. 91 - P. 6

(Here follows sheets of Tidal Volumes in Cubic Feet, marked Ex. 91, pp. 7 and 8.)

The quantity of "new" sea-water entering Upper Bay is:-

		In million cu.ft. per tidal cycle
At the Narrows -	Average for year	2,210
	Least amount (February)	670
	Least amount (Summer-August)	1,520

These figures were determined from daily observations by the salinometer, the records covering a period of over one year as made by the Metropolitan Sewerage Commission. The average of these observations is appended.

If no land-water entered the harbors then the water in the harbor would be as salty as that of the sea. The mean quantity of water flowing on ebb tide was divided into land and sea-water by means of the salinometer percentages. The land-water was then divided into "land-water which will return" and "land-water which will not return". The latter was taken as the run-off of the rivers for 12 lunar hours and the former as the remainder of the total land-water as shown by the salinometer.

The sea-water as shown by the salinometer was then divided by making the "sea-water which will not return" the same proportion of the total sea-water as the "land-water which will not return" is to the total land-water. This is so because the land and sea-waters are mixed, and the amount of "land-water which will not return" will take with it its proportionate amount of sea-water.

The division of water on flood tide was made by taking the total volume of flow on flood and laying off the amounts of land and sea-water which will return as shown on ebb. The remainder is the "new" sea-water, or the water which was not in the harbor on the preceeding tide. It must be equal to the "sea-water which will not return" as given on ebb.

The land-water as shown by the salinometer is always in excess of the run-off. This is so because the flushing action of the harbor is not complete, as at the end of every ebb tide there remains some land-water in the harbor. The amount remaining, which is the amount in excess of the run-off, is variable, due to the seasonal variations.

The amount of "sea and land-water which will not return" is not a large proportion of the amount of water flowing on an ebb tide. There is always a large amount of "water which will return" on the succeeding flood tide.

The amount of new sea-water is never a large proportion of the total amount flowing on a flood tide. This "new sea-water" is only new off places situated near the ocean and not new at such places as the Upper Bay, Hudson River, East River, or Newark Bay. At these places the "new sea-water" is really water which has not been at the place on a previous tide, but which comes from some other part of the harbor.

The water which causes the seaward trend is the amount of land-water flowing from the water-sheds above. For places near the ocean, this seaward trend is increased by some "sea-water which will not return;" but for places situated well within the harbor such "sea-water which will not return" is replaced by sea-water as explained above, which comes from some other part of the harbor and is not clean ocean water.

The "sea-water which will return" is always greatest during the summer months and is least during the spring months.

The "sea and land-water which will not return" is least during February and the summer months, and greatest during the spring and autumn months.

FLOOD CURRENT

Ex. 91 - P. 25

In addition to the preceding work which shows the divisions of land-water and sea-water at various places in the harbor, the following diagrams were made to show these changes geographically. That is, the information was plotted on the diagrams by locating the distances between the different places as abscissae and the mean tidal flows in cubic feet as ordinates.

In order to show the variation from mean conditions additional diagrams were constructed to show the division of land and sea-water during August and April when the minimum and maximum amounts of land-water are flowing. This work was done by using the salinometer records for the month recorded instead of the mean record for the year.

The diagrams showing the conditions existing in the East River were not divided up to show the water "which will return" and the water which will not return", as it was not possible to divide the waters of the East River in this manner, because, first the East River is a strait, open at both ends to bodies of salt water, and secondly, because the water sheds draining into the East River were so small that if a division had been attempted the divisions of "land-water which will not return" would be so small as hardly to appear thicker than a line on the diagrams.

Ex. 91 - P. 35

In the Upper Bay the quantities of new sea and land-water available for dilution of sewage are as follows:-

	In Million Cu.Ft. per Tidal Cycle.		
	New Sea-Water.	New Land-Water.	Total.
Average for year	2,210	1,180	3,390
Least amount (February)	670	690	1,360
Least amount (Summer-August)	1,520	620	2,140

If the quantity of water available for dilution of sewage is taken as the resultant flow through The Narrows, then the quantities are

	In Million Cu.FT. per Tidal Cycle.
Average for year	1,260
Least amount (Winter-February)	770
Least amount (Summer-August)	700

The course followed by sewage discharged at Robbins Reef would be similar to those shown by the float experiments made by the Metropolitan Sewerage Commission. The paths of these floats are given in diagrams in the Report of the Commission, dated 30th April, 1910.

The floats show that the currents oscillate with the tides. On flood tides the sewage is liable to travel about 6 miles, and on ebb about 10 miles.

A particle set adrift off Robbins Reef in the main channel on flood tide would take four tidal cycles to remain outside of Sandy Hook; and if started on ebb tide would take three cycles. It would take two tidal cycles for the particle to remain outside of the Narrows if started on flood and one cycle if started on ebb. All these estimates are based on the assumption that the particle will remain in the sea-ward trend of the current and not get delayed by cross currents.

The effect of undertow.

When the tidal currents turn from flood to ebb or from ebb to flood, the inertia of the moving stream plays a very important part. The turn of the tide takes place first along the shore. In The Narrows, the first change of current appears on the east side of the channel.

As the specific gravity of the sea outside of New York bar is about 1.024, the sea-water is approximately 2½ heavier than the fresh water discharged from the rivers. As the tide

turns there is a tendency for this lighter fresh water to flow out over the top of the incoming heavier salt water. There also is a tendency, largely due to inertia, for the formation of top and bottom currents flowing in opposite directions, and for side currents flowing contrarywise to the channel current. Consequently an "underrun" is formed. This term is distinctly applied to the current that predominates along the bed of a channel in the opposite direction to that flowing on the surface at the same time.

The "underrun" of salt water up the Hudson River extends above Poughkeepsie, where the water is often found brackish, during those seasons when the river discharge of land-water is small.

PEOPLE OF THE STATE OF NEW YORK v. STATE OF NEW JERSEY AND PASSAIC VALLEY SEWERAGE COMMISSIONERS.

IN EQUITY.

No. 2, Original. Argued November 8, 11, 12, 1918; restored to docket for further argument March 10, 1919; reargued January 25, 1921.—Decided May 2, 1921.

New York brought this suit against New Jersey and the Passaic Valley Sewerage Commissioners, to enjoin the execution of a project to convey the sewage of the Passaic Valley through a sewer system and to discharge it into a part of New York Harbor, known as the Upper New York Bay, the plaintiff alleging that the sewage would be carried by the currents and tides into the Hudson and East Rivers and be deposited on the bottom and shores of the Bay and upon and adjacent to the wharves and docks of New York City, and would so pollute the water as to render it a public nuisance, offensive and injurious to persons living near it or using it for bathing or for purposes of commerce, damaging to vessels using the waters, and so poisonous to fish and oysters in it as to render them unfit for food. The United States intervening opposed the plan as threatening, unnecessarily, obstruction of navigable channels, injury to the health of persons navigating the waters and of officials and employees at a navy yard, and damage to government property bordering on the Bay; but withdrew, without prejudice, upon the filing of a stipulation executed by its Attorney General, and by the defendant sewer commissioners acting under authority of an act of the New Jersey legislature, agreeing upon a modification of the method proposed for purifying and dispersing the sewage, specifying the results that must be secured thereby or through requisite additional lawful arrangements, allowing the Government full opportunity to inspect the workings of the sewer system and providing that compliance with the stipulation should be made a condition of any permit issued by the Government for construction, maintenance or operation. The case having proceeded to final hearing between the original parties,—

Held: (1) That the right of New York to maintain such a suit on behalf of her citizens was clear, without regard to the precise lo-

cation of the boundary between the two States or to New York's claim of jurisdiction over the waters of New York Bay. P. 301.

(2) That the defendant Sewerage Commissioners constituted a statutory, corporate agency of New Jersey, whose acts and intentions in the premises must be treated as those of the State. P. 302.

(3) That, if the conditions of the stipulation were realized and maintained, there could be no occasion for the injunction prayed for. P. 305.

(4) That the stipulation was binding on New Jersey and the United States. P. 307.

(5) That the evidence must be considered subject to the principle that, before this court will exercise its extraordinary power to control the conduct of one State at the suit of another, the threatened invasion of rights must be of serious magnitude and established by clear and convincing evidence. P. 309.

(6) That the evidence failed to prove that the proposed addition of sewage would cause increased damage to hulls of vessels or danger of air-borne disease to persons navigating or dwelling along the water, or (if treated as proposed in the stipulation) damage to persons bathing, or fish or oysters subsisting, in the water, additional to that attributable to existing discharge of sewage from New York City and its environs. P. 309.

(7) That, as to the question remaining, the evidence failed to show with the requisite certainty, that, even if treated only as specifically prescribed in the stipulation, the additional sewage would create a public nuisance by causing offensive odors, or unsightly deposits on the surface, or seriously add to the existing pollution; and that, therefore, and in view of improved methods of sewage treatment disclosed by the testimony and of the right of the Government to stop the operation of the sewer if it caused pollution of the Bay, the injunction must be refused. P. 310.

The court suggests that the problem involved in this case is one more likely to be wisely solved by cooperative study and by conference and mutual concession on the part of the States interested than by proceedings in any court. P. 313.

Bill dismissed without prejudice.

THIS original case was first argued at the October Term of 1918, but, owing in part to the time that had then elapsed since the closing of the evidence, the court found it necessary to direct the taking of additional testimony on certain specified points. See 249 U. S. 202. The

facts are reviewed in the opinion. No attempt is made to reproduce the arguments which were mainly concerned with the matters of fact involved.

Mr. Charles E. Hughes, with whom *Mr. Charles D. Newton*, Attorney General of the State of New York, *Mr. William J. O'Sullivan*, *Mr. Russell Lord Tarbox* and *Mr. Allen S. Hubbard* were on the brief, for complainant.[1]

Mr. Adrian Riker and *Mr. George W. Wickersham*, with whom *Mr. Thomas F. McCran*, Attorney General of the State of New Jersey, and *Mr. Robert H. McCarter* were on the brief, for defendants.[1]

Mr. Justice Clarke delivered the opinion of the court.

The People of the State of New York, in their bill filed in this suit, pray that the defendants, the State of New Jersey and the Passaic Valley Sewerage Commissioners, be permanently enjoined from discharging, as it is averred they intend to discharge, a large volume of sewage into that part of New York Harbor known as the Upper Bay, for the reason, as it is alleged, that such pollution of the waters of the harbor will be caused thereby as to amount to a public nuisance, which will result in grave injury to the health, to the property, and to the commercial welfare, of the people of the State and City of New York.

The Passaic River rises in the northeasterly part of

[1] At the first hearing, the case was argued by *Mr. Charles E. Hughes* on behalf of the complainant. *Mr. Merton E. Lewis*, Attorney General of the State of New York, and *Mr. William J. O'Sullivan* were on the brief. *Mr. Adrian Riker* and *Mr. Robert H. McCarter* argued on behalf of the defendants. *Mr. John W. Wescott*, Attorney General of the State of New Jersey, was on the brief.

New Jersey and empties into Newark Bay. High land separates its watershed from direct drainage into the Hudson River or New York Bay, and on the lower twenty-five miles of it there are located the cities of Paterson, Passaic, and Newark, and also a number of such large towns that the population upon and near to the river is treated throughout the record as approximately 700,000 in 1911, when it was thought the sewer would be completed, and as likely to be about 1,650,000 in 1940, to which year it was designed to furnish adequate sewerage capacity. These cities and towns, from their earliest settlement, had all drained their sewage into the river. The ebbing and flowing of the tide almost to Paterson delayed the escaping of this sewage from the river and resulted in the water becoming greatly polluted. This polluted water was emptied directly into Newark Bay, but, ultimately, 84% of it, modified, no doubt, by nature's agencies, but still polluted, found its way through the natural channel of Kill van Kull, into Upper New York Bay.

This drainage of sewage into the Passaic River resulted in the stream becoming such a menace to the health and property of the adjacent communities that, in 1896, a commission was appointed by the Governor of New Jersey, under the provisions of an act of the legislature, to study the problem presented, for the purpose of devising some system of sewage disposal which would afford relief. After this commission had reported, a second commission of investigation was provided for by act of the legislature in 1897, and its report was followed by a third similar commission in 1898.

The reports of these various commissions led, in 1902, to an act of the New Jersey legislature creating the Passaic Valley Sewerage District, with boundaries embracing substantially the entire watershed of the Passaic River, and to another act, in 1907, prohibiting the dis-

charge of sewage into the river after a date named, and directing the defendant Passaic Valley Sewerage Commissioners to prepare plans and specifications for a trunk sewer to dispose of the sewage and authorizing municipalities to contract with them for the service which they might require.

Under authority of this act, the defendant Sewerage Commissioners, in April, 1908, adopted a plan for sewage disposal, which provided for a main intercepting sewer, extending from the City of Paterson, along the right bank of the Passaic River, to a point in the City of Newark, and thence by a tunnel under the waters of Newark Bay and the cities of Bayonne and Jersey City to a point in Upper New York Bay about 500 feet north of Robbins Reef Light, where it was proposed to discharge the sewage at a depth of 40 feet of water below mean low tide. The estimated cost of the proposed sewer was $12,250,000.

It was provided in the act authorizing the construction of the sewer that, before any work should be undertaken or obligations incurred, a further investigation should be made by the Commissioners as to whether the discharge of the sewage into New York Bay would be likely to pollute its waters to such an extent as to cause a nuisance to persons or property within the State of New York, and that the result of such investigation, with the reasons for it, should be presented to the Governor of the State.

Such an investigation was made and upon report of the Commissioners the Governor concluded that the discharge of the sewage as proposed would not pollute the waters of New York Bay so as to cause a nuisance to either persons or property within the State of New York, and the Attorney General of the State also advised the Governor that in his opinion the State of New York could not have any valid legal objection to the use of the sewer as proposed.

There can be no doubt that the various commissioners

who investigated this subject were men of the highest character and intelligence and that they studied it with the aid of the best obtainable sanitary engineers, chemists and bacteriologists, for the purpose of arriving at a solution which would protect and preserve the interests of all of the great communities involved. It is equally beyond doubt that the Governor and other officials of New Jersey, with full appreciation of the magnitude and seriousness of the undertaking, proceeded with great caution and with a settled purpose to fully respect the rights of the people of the State of New York.

Learning of the plans of the State of New Jersey, thus detailed, the legislature of New York passed an act providing for a commission to investigate the probable effect upon the waters of New York Bay of the proposed Passaic Valley sewer, with power to coöperate with the authorities of New Jersey with a view to arriving at some mutually satisfactory solution of the problem. The record shows that various conferences were held between the New York Commission thus created and the Passaic Valley Sewerage Commissioners, but for some reason, which does not clearly appear, no mutually satisfactory course of action was arrived at, with the result that, in October, 1908, this suit for an injunction was commenced.

For the purpose of showing its right to maintain the suit, the bill thus filed sets out, with much detail, an agreement between the States of New York and New Jersey, approved by Congress in 1834, establishing the boundary line between the two States and giving to New York, to the extent therein written, exclusive jurisdiction over the waters of the Bay of New York.

But we need not inquire curiously as to the rights of the State of New York derived from this compact, for, wholly aside from it, and regardless of the precise location of the boundary line, the right of the State to maintain such a suit as is stated in the bill is very clear. The health,

comfort and prosperity of the people of the State and the value of their property being gravely menaced, as it is averred that they are by the proposed action of the defendants, the State is the proper party to represent and defend such rights by resort to the remedy of an original suit in this court under the provisions of the Constitution of the United States. *Missouri* v. *Illinois*, 180 U. S. 208, 241, 243; *Georgia* v. *Tennessee Copper Co.*, 206 U. S. 230.

Also, for the purpose of showing the responsibility of the State of New Jersey for the proposed action of the defendant, the Passaic Valley Sewerage Commissioners, the bill sets out, with much detail, the acts of the legislature of that State authorizing and directing such action on their part.

Of this it is sufficient to say that the averments of the bill, quite undenied, show that the defendant sewerage commissioners constitute such a statutory, corporate agency of the State that their action, actual or intended, must be treated as that of the State itself, and we shall so regard it. 180 U. S. 208, *supra.*

The remaining essential allegations of the bill are that the defendants are about to construct the sewer we have described and to discharge the sewage thereby collected into the Upper New York Bay, through a single opening 12 feet in diameter, at a point about half a mile north of Robbins Reef Light; that there would be about 120 millions of gallons of such sewage discharged into the Bay every 24 hours in 1911, and in excess of 357 millions of gallons by 1940; that such sewage would be carried by the currents and tides into the Hudson and East Rivers and would be deposited on the bottom and shores of the Bay and upon and adjacent to the wharves and docks of New York City, thereby so polluting the water as to render it: a public nuisance offensive and injurious to persons living near it or using it for bathing or for purposes of commerce, damaging to vessels using the waters, and

so poisonous to the fish and oysters subsisting within it as to render them unfit for food. To prevent the public nuisance, which it is averred would thus be created, a permanent injunction was prayed for.

The essential denials and allegations of the answer are as follows:

Admitting their intention to construct the sewer substantially as described, it is averred: that New Jersey has a shore line of 25 miles on New York Bay and on the Hudson River, and that large cities and towns of that State border upon the Bay, so that it has as important an interest as New York has in maintaining the waters free from pollution; that the sewer project objected to was authorized only after it had been recommended and approved by sanitary engineers of highest professional standing and experience and upon their assurance, after careful study of the tidal flow and currents of the Bay, that appreciable pollution would not be caused thereby; that the Passaic River empties into Newark Bay and its water, charged, under existing conditions, with the sewage collected from the same communities intended to be served by the projected sewer, in large part reaches New York Bay in the vicinity of Robbins Reef Light, by natural channels, without causing substantial injury to the water; and that the City of New York has long been discharging into the Bay at or near to the shore lines thereof, daily, more than seven times as great a volume of sewage (entirely untreated) as the daily discharge of the proposed sewer would be for many years to come. The answer concludes with further denials that the waters of the Bay would be corrupted or their usefulness impaired by the use of the proposed intercepting sewer.

After the defendants had answered, the Government of the United States, by leave of court, filed a Petition of Intervention. The warrant assigned for this intervention was, the power and duty of the Government with respect

to navigation and interstate commerce, and the inherent power which it has to act for the protection of the health of government officials and employees at the Brooklyn navy yard, and its duty to protect from damage the Government property bordering upon New York Bay.

The projected sewer was described in this Petition of Intervention, substantially as in the original bill, but it was averred that the plans for the removal of solids from the sewage were so indefinite and inadequate that the use of the sewer would result in the obstruction of navigation by the filling up and shoaling of the channels of the Bay, and that the proposed purification of the sewage was so insufficient that the waters would be rendered unsightly and unhealthful to persons using them for commerce or dwelling upon the adjacent shores. It was averred that there were other, better and more advanced methods of sewage disposal than those proposed, and that the threatened injury to commerce and navigation, to the public health and to the property of the United States was not necessary. For these reasons the Government joined in the prayer for relief.

The coming of the Government into the case was followed by conferences between its officials and the Sewerage Commissioners, with the result that a method of treatment of the sewage was decided upon much more thorough, comprehensive and definite in character than had been adopted before and the manner of dispersion of it at the outlet was so changed as to secure a much greater diffusion, at a great depth, in the adjacent waters.

These changes were ultimately embodied in a stipulation between the United States, acting through its Attorney General, and the Passaic Valley Sewerage Commissioners, acting under authority of a special act of the New Jersey legislature. It was agreed that upon the filing of this stipulation, properly executed, with the

Clerk of this Court, the Petition of Intervention of the Government should be dismissed, without prejudice—which was done on May 16, 1910.

The stipulation provides, with much detail, that at or near to a pumping station to be located in the Newark Meadows, near Newark Bay, the material coming from the trunk sewer shall first pass through coarse screens to remove floating matter; then through a grit basin or basins, to remove heavy matter, as far as practicable; then through self-cleaning mechanical screens, with openings of not over four-tenths of an inch; and then through sedimentation basins, equipped with "scum boards," at a prescribed velocity of flow. It is provided that the effluent thus screened and settled shall flow into a pumping well, whence it is to be pumped under pressure to a point near Robins Reef Light, where it is to be discharged at a depth of not less than forty feet beneath the surface of the water at mean low tide, through 150 outlets, distributed over an area of three and one-half acres, and so arranged as to drive the material horizontally across the tidal currents.

The terms of this stipulation were adopted by the Government under the advice of Army engineers of high rank and by the Sewerage Commissioners on the advice of distinguished sanitary engineers and it must be accepted as established by the testimony taken in 1919 that at that time screening and sedimentation and thorough dispersion in water through deeply submerged multiple outlets was regarded by the most competent authorities as the most approved method of disposing of sewage in large volume.

But, not satisfied with providing what was thought sufficient treatment to render the sewage innocuous, there was incorporated into the stipulation an agreement on the part of the Sewerage Commissioners that in the actual operation of the sewer at all times the following

results should be secured, either through compliance with the requirements of the stipulation for treatment of the sewage, "or through requisite lawful additional arrangements," viz: (1) There will be absence in the New York Bay of visible suspended particles coming from this sewage; (2) there will be absence of deposits caused by it objectionable to the Secretary of War of the United States; (3) there will be absence of odors due to the putrefaction of organic matter contained in the sewage; (4) there will be absence on the surface of the Bay of any grease or color due to the sewage; (5) there will be no injury to the public health due to the discharge of the sewage, and no public or private nuisance will be created thereby; (6) no injurious effect shall result to the property of the United States situated upon the Bay; (7) there shall not be a reduction in the dissolved oxygen content of the waters, due to this sewage, sufficient to interfere with major fish life. It is agreed that the Government shall have unrestricted opportunity to inspect the workings of the sewer system, by designated officials, and that full compliance at all times with the provisions of the stipulation referred to shall be made an express condition of any permit issued by the Government for the construction, maintenance or operation of the projected sewer system.

It is obvious that, if the conditions of this stipulation are realized and maintained, there will be no occasion or ground for such an injunction as was prayed for.

It is argued, however, and expert witnesses have testified, that the provisions therein stipulated for screening and sedimentation and final dispersion of the sewage in the water, are not sufficient to produce the results which the Sewerage Commissioners agree with the Government to produce and maintain, and that if such results as are feared by the witnesses are produced it would be impossible to determine whether they were caused by this

particular sewage or by that coming from other sources and that therefore the agreement would, in practice, be nugatory. But equally well informed and credible witnesses testified that the proposed treatment would produce the stipulated results and that the source of such pollution, if any should be caused by the Passaic sewage, could readily be traced to its origin, and we think the probabilities greatly in favor of this conclusion, having regard to the opportunity secured to the Government for inspection and observation of the treatment plant and for determining the quality and content of effluent before it is discharged into the Bay and the effect which it may have on the water in the immediate vicinity of the outlet.

It is also argued that this stipulation is not binding upon the State of New Jersey because executed only by the Sewerage Commissioners, and that it is invalid for want of power in the Attorney General to so stipulate on behalf of the United States.

But since by act of its legislature the State of New Jersey specifically authorized the Sewerage Commissioners to execute the stipulation and by its special counsel entered of record its approval of, and consent to, it, we must and do regard it as the valid obligation of the State as certainly as of the Commissioners.

As to the United States: The intervention of the Government was allowed upon allegations that the inadequate treatment of the sewage proposed would result in injury to navigation and commerce: by causing deposits of solid matter, to the extent of thousands of tons annually, which would fill up and shallow the channels of the Bay; by rendering the Port of New York less serviceable and attractive to commerce and offensive and unwholesome to persons using and living near it; and by causing injury to the hulls of vessels by the character of the effluent to be discharged. It was also averred that

practically irreparable damage would be caused to extensive properties owned by the Government adjacent to the Bay.

Having regard to the large powers of the Government over navigation and commerce, its right to protect adjacent public property and its officers and employees from damage and disease, and to the duty and authority of the Attorney General to control and conduct litigation to which the Government may be a party (Rev. Stats., §§ 359, 367), we cannot doubt that the intervention of the Government was proper in this case and that it was within the authority of the Attorney General to agree that the United States should retire from the case upon the terms stated in the stipulation, which were plainly approved by the Secretary of War, who afterwards embodied them in the construction permit issued to the Sewerage Commissioners.

Although this stipulation was filed and the Government withdrew from the case on May 16, 1910, the remaining parties went forward and took a great volume of testimony, the taking of which was concluded in June, 1913. Five years passed before the case was brought on for argument at the October Term, 1918, and upon examination this court, having regard to the long time which had elapsed since the taking of testimony was closed and to the rapid advance in sanitary science then in progress, suggested in the record, directed that additional testimony should be taken in order that the court might be advised: (1) As to any practicable modification of the proposed sewer system which might improve it and reduce any polluting effect upon the water which might be caused by the effluent to be discharged; (2) as to any practicable plan or arrangement for sewage disposal which would lessen the polluting effect derived from the New York City sewage; (3) and as to the present degree of pollution of the waters of New York Harbor

and the change in this respect since the taking of the testimony was closed.

In compliance with this order much additional testimony was taken.

With the record in this state we come to consider the evidence introduced, but subject to the rule that the burden upon the State of New York of sustaining the allegations of its bill is much greater than that imposed upon a complainant in an ordinary suit between private parties. Before this court can be moved to exercise its extraordinary power under the Constitution to control the conduct of one State at the suit of another, the threatened invasion of rights must be of serious magnitude and it must be established by clear and convincing evidence. *Missouri* v. *Illinois*, 200 U. S. 496.

The water of New York Bay is such a brackish combination of salt sea and fresh water that it could not, under any circumstances, be used for drinking or other domestic purposes and, therefore, the reasons given in the bill to justify the injunction prayed for are restricted, as we have seen, to the claims that the addition of the Passaic Valley sewage to the already polluted waters of the Bay would result, in odors offensive and unwholesome to persons bathing in them or passing over them in large vessels or in small boats or living and working upon the adjacent shores, in causing unsightly deposits on the surface of the water and chemical action injurious to the wood and metal of vessels navigating the Bay, and in rendering fish and oysters taken from such waters unfit for consumption.

The evidence introduced, as to increase of damaging chemical action upon the hulls of vessels by the proposed addition of sewage, and as to danger from air-borne diseases to persons using the water in boats and vessels or working or dwelling upon the shore of the Bay, is much too meager and indefinite to be seriously considered as

ground for an injunction, and when it is considered that for many years all of the sewage from the great population of New York City and its environs and from the large cities on the New Jersey shore (estimated, in 1912, at 900 millions of gallons daily) has been discharged into the harbor, quite untreated, the evidence does not justify the conclusion that persons bathing in or that fish or oysters subsisting in such waters can sustain much further damage from the addition to them of the sewage of the Passaic Valley, after it has been treated in the manner proposed in the stipulation with the Government.

There remains to be considered, therefore, only the offensive odors, and unsightly deposits on the surface which it is claimed will be caused by the addition of putrescible matter to the water, and it is to this claim that a large part of the evidence introduced by the complainant is directed. Much evidence was introduced tending to prove that sewage collected from so great an area as that of the Passaic Valley Sewerage District would be stale, if not septic, when it reached the treatment plant at Newark Bay and that it would, therefore, hold in solution much organic matter which would not be removed by the screening and sedimentation processes proposed, with the result that it would cause disagreeable deposits on the surface of the water—"oily and sleek fields"—and offensive odors near the place of discharge and upon the wharves and shores adjacent to the Bay.

On the other hand witnesses of seemingly equal candor and learning, and with large practical experience, called by the defendants, testified that they were confidently of the opinion that the treatment of the sewage provided for in the stipulation with the United States would cause such purification of it that the results guaranteed therein would be fully realized.

It is much to be regretted that any forecast as to what the effect would be of the treatment and deeply sub-

merged discharge through multiple outlets proposed for this large volume of sewage must depend almost entirely upon the conflicting opinions of expert witnesses, for experience with such treatment and dispersion under even approximately like conditions seems entirely wanting. It is, however, of much significance that the authorities of the City of New York, after many years of investigation of the subject of sewage disposal, in their latest plans propose to adopt a treatment of screening and sedimentation and dispersal in deep water very similar to, but not so extensive and thorough as, that provided for in the stipulation between the defendants and the United States.

There is only one point upon which all the experts called for the opposing parties agree, viz.: that in the present state of learning upon the subject the amount of dissolved oxygen in water is the best index or measure of the degree to which it is polluted by organic substances, it seemingly being accepted by them all that upon the oxygen content in water depends its capacity for digesting sewage—that is for converting organic matter into inorganic and harmless substances by direct oxidation and by sustaining bacteria which assist in such conversion.

The witnesses agree that so long as there is sufficient dissolved oxygen in the water the process of digestion of the sewage will go forward without producing offensive odors and that when it sinks below a required percentage of saturation such odors will appear, but, unfortunately, there is a wide divergence of opinion among them as to what the required lower percentage is. The opinions of seemingly well qualified experts vary in giving from 25% to 50% of saturation as the amount of oxygen necessary to prevent the appearance of such offensive odors from decomposition of organic matter.

Measured by this dissolved oxygen standard, the evidence of the complainant is that as early as 1906 the

water adjacent to New York City, especially in the Bronx and lower East River, was much polluted by sewage, but that the water in other parts of the Bay, especially near Robbins Reef Light was somewhat, but not greatly, contaminated. This condition, the evidence shows, continued with no very pronounced decrease in the oxygen content of the water until 1911 when the investigations embodied in the first testimony taken were concluded. And the evidence taken under the order of the court in 1919 shows an irreconcilable conflict in the testimony as to the then condition of the water, especially near Robbins Reef Light, and as to the probable condition of it to be anticipated in the future. In the interval from 1906 to 1919 the estimated growth of the population of New York City and its suburbs draining sewage into adjacent waters was in excess of 100,000 a year—an increase of population in the aggregate much greater than the total population of the Passaic Valley Sewerage District at present, and approximately equal to its estimated population in 1940—and it is undisputed that this New York sewage, untreated, was discharged from over 450 sewers directly into the adjacent waters, for the most part at or above the line of low tide, and that only in a few instances was it carried even to the pier heads.

It would seem, therefore, that, if the anticipations of the experts for the complainants, as to the results likely to be produced by the effluent from the sewer of defendants, were well founded, by the year 1919 conditions in the harbor should have become so pronounced and plain that there could not have been such conflict as the record shows in the testimony of trustworthy and competent scientists as to its then existing condition.

Considering all of this evidence, and much more which we cannot detail, we must conclude that the complainants have failed to show by the convincing evidence which the law requires that the sewage which the defendants intend

to discharge into Upper New York Bay, even if treated only in the manner specifically described in the stipulation with the United States Government, would so corrupt the water of the Bay as to create a public nuisance by causing offensive odors or unsightly deposits on the surface or that it would seriously add to the pollution of it.

The evidence taken in 1919 also discloses that other means than those specifically described in the Government stipulation may be resorted to, if needed, for the purpose of improving the character of the effluent from the sewer, viz.: slower and more prolonged sedimentation processes; additional screening; the aëration of the sewage before it reaches the treatment plant and again after treatment and before discharge into the tunnel conveying it to the Bay; and finally, if required, chemical treatment.

Having regard to the treatment of the sewage prescribed in what we regard as a valid contract on the part of the defendants with the Government of the United States, to the specific agreement therein for protection of the waters of Upper New York Bay from pollution, and to the means which the Government will have to secure further purification, if desired, by refusing to permit the discharge of sewage into the Bay to continue, we conclude that the prayer for injunction against the operation of the sewer must be denied.

We cannot withhold the suggestion, inspired by the consideration of this case, that the grave problem of sewage disposal presented by the large and growing populations living on the shores of New York Bay is one more likely to be wisely solved by coöperative study and by conference and mutual concession on the part of representatives of the States so vitally interested in it than by proceedings in any court however constituted.

The court, recognizing the importance of the ruling which it is making to the great populations interested,

as well in the State of New Jersey as in the State of New York, will direct that the decree denying the relief prayed for shall be without prejudice to the instituting of another suit for injunction if the proposed sewer in operation shall prove sufficiently injurious to the waters of the Bay to lead the State of New York to conclude that the protection of the health, welfare or commerce of its people requires another application to this court.

It results that the bill of complainant will be dismissed but without prejudice to a renewal of the application for injunction if the operation of the sewer of defendants shall result in conditions which the State of New York may be advised requires the interposition of this court.

Bill dismissed without prejudice.
